X-raying military men 670 - misc

CASE RECORDS  
OF THE MASSACHUSETTS GENERAL HOSPITAL  
ANTE-MORTEM AND POST-MORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

VOLUME 27

1941

INDEX  
CASE RECORDS OF THE  
MASSACHUSETTS GENERAL HOSPITAL  
VOLUME 27  
1941

The date of publication of any case may be determined from the case number. The first two figures of each case number indicate the volume number, 27. The third and fourth figures give the number of the week, dating from January 1. The last figure gives the case number for the week. For example, Case 27352 is the second case for the 36th week of Volume 27.

- Abcess, of kidney, 27162  
of liver, 27071, 27141, 27431, 27441  
of lung, 27162  
of peritoneum, 27462  
of prostate, 27162
- Adenocystoma of pancreas, 27231, 27262
- Adenoma, of bronchus, 27511  
of ovary, testicular, 27161  
of pancreatic islet cells, 27151  
of parathyroid, 27311  
of pituitary, 27291
- Adrenal, carcinoma of, 27352  
neuroblastoma sympathicum of, 27392  
pheochromocytoma of, 27022
- Anemia (See Blood, diseases of)
- Aneurysm, dissection, of aorta, 27022, 27292, 27302  
ruptured, of circle of Willis, with subarachnoid and intracerebral hemorrhage, 27512  
(See also Syphilis)
- Anomaly, congenital, atresia of extrahepatic biliary system, with agenesis of gall bladder and common duct, 27021  
Ectopic pancreas in stomach, 27182  
(See also Heart)
- Aorta, suppurative aneurysm of, 27302, 27442  
with rupture, 27401, 27442
- Appendicitis, acute, with perforation, 27211
- Artery, periarthritis nodosa, 27011, 27371  
Temporal arteritis, 27252  
(See also Aneurysm, Embolism, Heart)
- Arthritis, chronic rheumatoid, 27331, 27472
- Ayres's disease, 27371
- Bile duct, carcinoma of, 27451  
stone in, 27071
- Bladder, carcinoma of, 27172
- Blood, diseases of  
Anemia, aplastic, 27352  
sickle-cell, 27421  
Erythroblastosis fetalis, 27031  
Polycythemia vera, 27352
- Bone, carcinoma of, 27362  
metastatic, 27461  
epithelioma of, 27152
- Bone marrow, lymphoma of, reticulum-cell type, 27131
- Brain, carcinoma of, metastatic, 27131, 27192  
hemangioma of, 27311  
hematoma of, subdural, 27472  
hemorrhage of, 27351, 27512  
infarct of, 27322, 27331  
keratosis of, 27031  
meningioma of, cerebral, 27331
- Brain, adenoma of, 27311
- Cholecystitis, of bile duct, 27451  
chronic, with stone, 27401  
with perforation, 27241  
of duodenum, 27091, 27092  
of gall bladder, 27221, 27232, 27481  
of liver, 27232, 27362, 27481  
metastatic, 27411  
of lung, bronchiogenic, 27181, 27192, 27391  
of ovary, cystadenoma, 27411  
of pancreas, 27481  
of rectum, 27252  
of salpinx, adeno-, 27102  
of sigmoid, with perforation, 27452, 27462  
of stomach, 27171, 27202, 27212  
with ulceration, 27271  
of uterus, adeno-, 27072, 27172  
of vertebra, metastatic, 27461
- Cholangitis, acute, 27071, 27431
- Choledocholithiasis, 27071
- Cirrhosis, see Liver
- Colitis, see Intestine
- Cyst, dermoid, of mediastinum, 27052, 27191
- Embolism, pulmonary, 27412, 27432
- Emphysema, pulmonary, 27192
- Empyema, encapsulated, 27522
- Endarteritis, pulmonary, 27131, 27371
- Endocarditis, see Heart
- Enteritis, see Intestine
- Ewing's tumor of fibula, 27112
- Femur, osteomyelitis of, 27122
- Fibroma, neuro-, of mediastinum, 27312, 27332
- Fibula, Ewing's tumor of, 27112
- Fistula, vesicovaginal, 27172
- Gall bladder  
carcinoma of, 27221, 27232  
metastatic, 27411
- Gout, 27351
- Heart  
congenital, interventricular septal defect, ? bicuspid aortic valve, 27261  
Cor pulmonale, 27131, 27192, 27371, 27382  
coronary disease of, thrombosis, 27062, 27132, 27291, 27432  
Endocarditis, bacterial, acute, 27222, 27522  
subacute, aortic, 27261  
calcareous, aortic, with stenosis, 27012  
rheumatic, acute  
aortic, with stenosis, 27261, 27521  
mitral, with stenosis, 27521  
pulmonary, 27521  
tricuspid, 27521  
rheumatic, chronic  
aortic, with stenosis, 27121, 27261  
mitral, with stenosis, 27121, 27412  
tricuspid, 27121

- Hemopericardium, 27132, 27401
- infarct of, 27062, 27411, 27432
  - with rupture, 27132
- lymphoma of, reticulum cell type, 27261
- Myocarditis, acute, 27342
  - rheumatic, 27421
- Pericarditis, acute, 27342, 27371
  - (See also Aorta and Syphilis)
- Hemangioma, of brain, 27201
  - cavernous, of rib, 27341
- Hematoma, subdural, 27472
- Hemochromatosis, of liver, pancreas, thyroid gland and lymph nodes, 27142
- Hemorrhage, cerebral, 27351, 27512
  - subarachnoid, 27512
- Hodgkin's disease, see Lymphoma
- Humerus, osteogenic sarcoma of, with ossifying metastases in regional lymph nodes, 27501
- Ileum, see Intestine
- Ileus, gallstone, 27082
- Ilium, carcinoma of, metastatic, 27461
- Infarct of brain, 27522
  - of lung, 27062, 27371, 27372, 27412, 27421, 27451, 27471
  - of spleen, 27522
  - (See also Heart)
- Intestine, carcinoma of, 27091, 27092, 27252
  - with perforation, 27241, 27452, 27462
  - metastatic, 27411
- Colitis, ulcerative, acute idiopathic, with perforation, 27242
  - diverticulitis of, 27252
  - diverticulosis of, 27462
  - ileitis, regional, idiopathic, 27032
  - lymphoma of, reticulum cell type, 27451
  - obstruction of, 27082, 27321
  - perforation of, 27452
  - polyposis of, 27241
  - ulcer of, perforating, 27051
  - volvulus of, 27321
- Kernicterus, 27031
- Kidney, abscess of, 27162
  - carcinoma of, metastatic, 27172
  - glomerulosclerosis of, intercapillary, 27381
  - hypernephroma of, 27461
  - lymphoma of, reticulum-cell type, 27451, 27471
  - (See also Nephritis)
- Leukemia, see Blood
- Lipoma of hepatic flexure, 27042
- Liver, abscess of, multiple, 27071, 27141, 27431, 27441
  - carcinoma of, 27232, 27481
  - cirrhosis of, alcoholic, 27081, 27322, 27361, 27522
  - cardiac, 27521
  - portal, 27362
  - toxic, 27331
  - hemochromatosis of, 27142
  - hepatoma of, 27362
- Lung, abscess of, 27162
  - carcinoma of, bronchiogenic, 27181, 27192, 27391
  - metastatic, 27172, 27232, 27362
  - embolism of, 27412, 27432
  - emphysema of, 27192, 27382
  - Endarteritis, 27131
  - fibrosis of, 27382
  - hemorrhage into, 27442
  - infarct of, 27062, 27371, 27372, 27412, 27421, 27432, 27471
  - lymphoma of, reticulum-cell type, 27111, 27451, 27471
  - periarthritis nodosa of, 27371
  - pneumonia of, 27351
  - tuberculosis of, 27251
- Lupus erythematosus, acute disseminated, 27301, 27371, 27402, 27502
- Lymph Nodes, hemochromatosis of, 27142
- tuberculosis of, 27441
- Lymphoma, reticulum-cell type, of heart, 27281
  - of kidney, 27451, 27471
  - of lung, 27111, 27451, 27471
  - of marrow femoral 27131
  - of mediastinum 27111
  - of omentum 27451
  - of ovary, 27281, 27451
  - of peritoneum 27281
  - of pleura 27111, 27451
  - of retroperitoneal tissue 27111
  - of sigmoid 27451
  - of stomach 27111
  - of trachea 27111
- Mediastinum carcinoma of mediastinum 27192 27451
- cyst of, dermoid, 27052 27191
- fibroma of, neuro-, 27312 27332
- lymphoma of reticulum-cell type 27111
- Mycosis fungoides 27352
- Myeloma plasma cell, diffuse 27131
- Myxedema postoperative, 27142
- Nephritis glomerulo-, subacute 27011
- pyelo- acute 27222, 27342 27377
- chronic, 27222, 27282
- Necrosis (?) 27372
- Neuroblastoma sympatheticum of adrenal 27392
- Omentum lymphoma of reticulum-cell type 27451
- Osteitis fibrosis cystica 27311
- Osteoma, osteoid of tibia 27492
- Osteomyelitis of radius 27491
- subacute, of femur, 27122
- Ovary adenoma of testicular 27161
- carcinoma of, 27411
- metastatic, 27451
- lymphoma of reticulum cell type 27281 27451
- Pancreas, adenocystoma of, 27231, 27262
  - adenoma of, 27151
  - carcinoma of, 27481
  - ectopic in stomach, 27182
  - hemochromatosis of, 27412
- Pancreatitis, acute, 27041, 27482
- Parathyroid, adenoma of, 27311
- Perforation of sigmoid, 27452 27462
- Periarthritis nodosa, 27011, 27371
- Peritonium, abscess of, 27462
  - carcinoma of, metastatic, 27212, 27481
  - carcinosis of, 27411
  - lymphoma of, reticulum cell type 27281
- Peritonitis, acute, 27141, 27371, 27452, 27462, 27482
- tuberculous, 27441
- Pheochromocytoma of adrenal, 27022
- Pituitary, adenoma of, 27291
- Pleura, carcinoma of, metastatic, 27481
- carcinosis of, 27411
- lymphoma of, reticulum-cell, 27111, 27451
- Polyserositis, 27371
- Prostate, abscess of, 27162
- Radius, osteomyelitis of, 27491
- Rectum, see Intestine
- Rib, hemangioma of, cavernous, 27341
- Sigmoid, carcinoma of, adeo-, 27102
- Sarcoma, fibro-, of stomach, 27272
  - neurogenic, 27061
  - lympho-, see Lymphoma
  - osteogenic, of humerus, with ossifying metastases in regional lymph nodes, 27501
  - reticulum-cell (See Lymphoma)
- Septicemia, staphylococcal, 27162

Spleen, carcinoma of, metastatic, 27411  
 infarct of, 27522

Stomach, ectopic, calcareous, 27012

Stomach, anomaly, congenital, ectopic pancreas in, 27182  
 carcinoma of, 27171, 27202, 27212  
   with ulceration, 27271  
 lymphoma of, reticulum cell type, 27111  
 sarcoma of, fibro, 27272  
   neurogenic, 27061  
 ulcer of, with perforation, 27331

Syphilis, of, aorta, 27261, 27302, 27442  
   with aneurysm, rupture of, 27401, 27442  
 of tibia, 27152

Tabs, dorsalis, 27261

Thrombosis of hepatic vein, 27431  
 of vena cava, 27111  
 (See also Heart, coronary disease of)

Thrombus, tumor, of hepatic vein and inferior vena cava, 27362

Thyroid gland, hemochromatosis of, 27142

Tibia, osteoma of, osteoid, 27492  
 periostitis of, syphilitic, 27152

Trachea, lymphoma of, reticulum cell type, 27111

Tuberculosis, of lung, 27251  
 of lymph nodes, 27411  
 miliar, 27251, 27441

Ulcer, of duodenum, acute perforating, 27051  
 of stomach, with perforation, 27331

Uterus, carcinoma of, 27072, 27172  
 bleeding of, "functional," 27101

Vein, thrombosis of, 27111, 27431

Vena Cava, thrombosis of, 27111  
 thrombus, tumor of, 27362

Ventricles, carcinoma of, metastatic, 27461

Vitamin A deficiency, 27251

Volvulus, of terminal ileum, 27321

## MENTAL-HYGIENE CLINICS

SALOMON GAGNON, MD\*

BOSTON

MENTAL illness and its related problems are matters for public concern. The community is very sensitive to matters of public health, but generally its interest does not include mental disorders, the greatest and commonest of all menaces. Epidemics of typhoid fever, scarlet fever, diphtheria, infantile paralysis and encephalitis promptly arouse the people and the public authorities to action for preventive and remedial steps, but mental illness,<sup>1</sup> which takes nearly as great a yearly toll in morbidity as all the above combined (72 per cent),<sup>2</sup> does not elicit more than casual notice. The lay public is not alone in this attitude of *laissez faire*. Professional men and women, including many physicians, do not appear greatly alarmed and, one can safely say, are not cognizant of the magnitude of this menace. Nevertheless it is responsible for the hospitalization of thousands of people each year in this country, and costs much in the way of grief, unhappiness and money. It is time that the people realized that this menace of mental illness is their problem. Much has already been accomplished by a handful of pioneers, but more widespread interest and action are necessary.

In this paper I shall not go into the history of the development of the methods applied to solve this problem, but shall emphasize one procedure that appears to offer great promise. It is generally agreed that there are three principal ways of attacking mental illness: hospitalization of the mental patient after full development of the illness and marshaling, in the hospital centers, the modern methods of care and treatment; prevention by reaching the maladjusted and the predisposed before the illness has reached the stage requiring specialized care and treatment in a mental institution; eradicating these disorders by prophylaxis or specific methods based on increasing the opportunities for research and the discovery of the etiologic factors.

Hospitalization is necessary for most of the well-established psychoses, and treatment is carried out in a satisfactory manner in most institutions; this alone is inadequate, however, as witnessed by the marked overcrowding of all mental hospitals.<sup>3</sup>

Should more hospitals be constructed, or should more buildings be added to existing ones? A hospital plant involves a minimum initial outlay of millions, \$5,000,000 being about the average figure for a 2000 bed hospital. The annual maintenance cost of such a hospital is approximately \$800,000. This is a tremendous burden on the taxpaying public, and an attempt should be made to find less expensive methods of controlling mental disease. It appears desirable, therefore, to slacken the pace of the building program, at least from an economical point of view.

The other two methods mentioned above offer much promise and involve only a small fraction of the cost of constructing and maintaining additional buildings. The expenditure for research in Massachusetts, as well as in other states, is very difficult to determine accurately, but it is most certainly a very small proportion of the total expenditures for mental illness. Research facilities should be greatly increased at strategic locations in hospitals that offer the best opportunities. All hospitals, however, should be given sufficient stimulus to make a contribution.

The purpose of this paper is to stress the value of the so-called "mental-hygiene clinics," including child-guidance and habit clinics. Much has already been done by the establishment of child-guidance and habit clinics throughout the country, particularly in Massachusetts. More adequate co-ordination of the clinic work should be fruitful of results. The significance of the early detection and treatment of the maladjusted cannot be over-emphasized, but it seems equally important to expand clinical facilities to include those people beyond the age of fourteen years at the period of their lives when the first obvious manifestations

\*Chief executive officer, Boston Psychopathic Hospital; instructor in psychiatry, Tufts College Medical School.

of mental disease become apparent. There is no definite evidence to prove that the behavior patterns as seen in the child-guidance and habit clinics lead to mental illness or are the prodromal symptoms.

The adult mental-hygiene clinic appears to offer the most practical value. I was connected with such a clinic sponsored by the Danvers State Hospital and operated at the Lynn General Hospital,

Lynn, Massachusetts. The clinic was held one-half day each week and was conducted by one psychiatrist and one psychiatric social worker. The services of a psychologist were obtained when needed. The appended statistics were compiled to point out the types of cases seen at the clinic and the probable factors involved, and to promote pertinent comments and constructive thoughts.

The total number of patients treated from 1929 to 1934, inclusive, was 255. The diagnosis most frequently made, as shown in Table 1, was psychoneurosis, 127 cases, or 50 per cent of the total, being so diagnosed. Fourteen cases, the next lar-

gest group, were diagnosed as mental deficiency, and 11 as manic-depressive psychosis. The diagnosis of situational reaction was made in 10 cases, and that of neurotic adolescent in 9.

It appears, then, that the so-called "functional" or psychogenic conditions comprise the bulk of the cases treated. It is well to note, however, that neurotic symptoms may sometimes be the early or incipient stages of more malignant conditions, such as dementia praecox. These cases, if properly handled, should not progress to the more malignant conditions. There is no way to determine whether or not this will be true of the series reported here, but thus far no case with neurotic symptoms has progressed to either dementia praecox or any other malignant condition.

Forty-seven definitely psychotic patients were also seen at the clinic, including 11 diagnosed as manic-depressive psychosis, 7 as dementia praecox and 5 as central-nervous-system syphilis. Of these psychotic patients only 2 were committed on clinical recommendation or otherwise. Commitment was recommended in another case diagnosed as manic-depressive psychosis, depressed type, because of the severity of the symptoms and the inadequacy of the supervision. This recommendation was not followed, and the patient finally committed suicide. Therefore, of 47 psychotic patients, 44 could be satisfactorily handled at home under clinical supervision and treatment. The majority of these patients would, without question, have been committed if clinical services had not been available. The cost of the hospitalization of this group of 44 patients represents thousands of dollars. It is estimated that the average weekly per capita cost in all the state institutions is approximately \$8.00.<sup>4</sup> The average hospital residence of a mental patient is roughly four years. Therefore, on the basis of these figures, the

TABLE 2. *Etiologic Factors.*

FACTOR	No. OF CASES
Economic stress and employment conditions	121
Marital and sexual difficulties	118
Childhood conflicts	116
Physical conditions	84
Social adaptation	26
Hereditary factors	18
Alcoholism	12
Psychic trauma	11
Low degree of intelligence	10
Personality difficulties	8
Religious factors	4

hospitalization of a patient for four years would cost \$1664, and the hospitalization of 44 patients on the same basis would amount to a total of \$73,216. This apparently represents the saving effected by a clinic very limited in its scope and personnel.

In considering the factors involved (Table 2),

it is noteworthy that only 18 cases, or about 7 per cent, showed heredity factors that could be uncovered by searching social-service investigation. Environmental factors were found to exist in the majority of cases. Economic stress or difficulty in employment was present in 121 cases, or 47 per cent of the total. The economic factor was not the only factor in most cases, and it is difficult to evaluate its relative importance. Physical condition or disease is another significant factor. It was found to be present in 84 patients. Again, its influence on the patient's mental condition is difficult to evaluate. Childhood conflicts of various types were present in 116 cases. These conflicts originated from an oversolicitous mother in 21 patients, unwholesome home in 20, friction between parents in 12, broken home in 11, and a neurotic mother in 11. It may be significant that in only one patient were hardships of childhood considered important. Marital and sexual difficulties were present in 118 cases. Maladjustments of this type are undoubtedly bound up with profound personality difficulties or defects that do not permit adult, mature adaptation. The enumeration of the factors within the home and involving intimate, interpersonal relations looms large in the production of maladjustment, neurotic manifestations and other abnormal mental reactions.

Some emphasis might be placed on the importance of the economic situation in the family circle. Economic stress interferes with the quality of the life of most individuals and of the family group. There is an uncertainty concerning the opportunity of securing the necessities and the niceties of life, and this involves their fundamental, instinctive demands. It impinges daily in a very definite way on the fullness of the life of the individual and interferes with his relations with his fellow men. During a century of industrialism, more emphasis has been placed on the importance of acquisition, and this, along with bla-

tant exhibitions of wealth, has created in the minds of the less fortunate a feeling of envy, dissatisfaction and insecurity. Wealth and economic independence acquired for their own sake, or for the power they endow, are surely not insurance against mental deviations, but they do permit a better and more healthful mode of living. Money, in another way of thinking, also permits indispensable initiatives and the expansion of individual activity. Innumerable frustrations can rightfully be laid at the door of economic inferiority. Gone are the times when people were satisfied with little and content to live submissively with the simple satisfactions that became their heritage. Their sense of relative values has become profoundly modified.

#### SUMMARY

Those responsible for the care of the mentally ill have been active in promoting the idea of early treatment of incipient and acutely ill patients to prevent much of the accumulation of chronic cases that require costly and prolonged hospitalization.

Specialized clinics of the type discussed in this paper, and institutions dealing primarily with acute material, such as the hospitals in the psychopathic system, appear to be worthy of considerable expansion.

A statistical survey is made of a mental hygiene clinic dealing with the diagnostic groups treated and the probable factors involved.

## SO-CALLED "MESENTERICOPARIETAL HERNIA"

## Report of a Case

HENRY W. HUDSON, JR., M.D.\*

BROOKLINE, MASSACHUSETTS

THE following case of imprisonment of the small intestine, owing to a congenital defect in the mesocolon, is reported because of the rarity of the condition.

## CASE REPORT

F.R., an 8-year-old schoolboy, entered the Peterboro, New Hampshire, Hospital on August 1, 1939, complaining of severe abdominal pain. The family and past histories were noncontributory except for an indefinite history, extending back for more than a year, of poorly localized attacks of abdominal pain lasting from 1 to 3 hours and unaccompanied by vomiting, fever or evidence of infection.

During the morning of the day before admission, the patient rode horseback and appeared to be well. He refused luncheon and later refused his supper, but made no complaint until the night preceding admission, during which his sleep was restless and he complained of abdominal pain. The boy stated that he had had a stool during the afternoon before admission, but this statement could not be corroborated. By morning he was complaining bitterly of abdominal pain, which he referred to the mid-abdomen and to the right side. He did not vomit or complain of nausea. On admission the mouth temperature was 98.6°F., the pulse rate 70, and the white-cell count 4000 with 53 per cent polymorphonuclears. The local physical examination was made with difficulty, but his physician, Dr. Donald Clark, found tenderness in the right lower quadrant without other positive physical findings in the abdomen. Rectal examination revealed a large amount of inspissated feces and tenderness more marked on the right side.

Two enemas were administered and were returned with formed fecal masses. Pain appeared to be aggravated by the enemas, and the patient spent the morning in a knee-chest position, which he assumed because of pain. One examination of the urine was negative. At noon the white-cell count had risen to 12,000, and the polymorphonuclears had increased to 90 per cent. There had been no vomiting and no apparent nausea.

Shortly after 1 p.m., I examined the patient in company with Dr. Clark. The child was in bed in the knee-chest position, which could be altered only after great protest. He would consent to be on his left side with the lower extremities flexed on the abdomen, and with great difficulty he was persuaded momentarily to be recumbent with the legs extended. The mouth temperature was then 99°F., the pulse 64. The facies were expressive of pain, the skin was cool and clammy, but he did not appear to be in deep shock. The general physical examination was not remarkable. The abdomen was not distended, and there was no intestinal patterning or visible peristalsis. There was no muscle spasm, but there was excruciating tenderness throughout the right side of the abdomen, with no recognized point of maximum tenderness. Palpation of

the left side of the abdomen caused no pain. No masses were felt. Rectal examination was negative. During examination the child appeared nauseated but did not vomit.

Laparotomy was performed at 2 p.m. without a pre-operative diagnosis having been made.

Under avertin and ether anesthesia, an incision, which was eventually extended from the right costal margin to the pubis, was made and the peritoneum incised without incident. The omentum presented, and with it the large intestine, identified as the transverse and left colon. The stomach, liver and gall bladder were normal in appearance and position. A large, thin-walled, transparent hemispherical peritoneal sac occupied the greater part of the abdominal cavity. Through the sac, coils of intestine were visible. The sac was incised, exposing the small intestine, appendix and cecum. The exposed small intestine was slightly cyanotic, and there was a volvulus of 180° in a clockwise direction. This was reduced, with improvement in the color of the bowel. With the volvulus reduced, the entire small intestine lay anterior to the transverse colon and toward the right side of the abdomen. Further exploration, with the transverse colon and omentum elevated, revealed a defect in the mesocolon adjacent to the last part of the duodenum and ligament of Treitz. Through this defect, the small intestine appeared to have passed progressively, beginning with the jejunum and continuing until the appendix, cecum and ascending colon had also passed through the defect. By exerting traction,—first on the right colon, then on the cecum, then on the ileum and finally on the jejunum,—the small intestine was withdrawn until it came to occupy its normal position below and behind the transverse colon. With this accomplished, the color of the bowel was good, and it was possible to place the intestinal tract in its normal position. The cecum and ascending colon were unduly mobile, and the ascending mesocolon was represented by a peritoneal reflection from the right ilio-lumbar fossa.

These several manipulations were not accomplished without the expenditure of a good deal of time and handling of the bowel. It therefore seemed unwise to prolong the operation by seeking to determine the distribution of the blood supply to the bowel. The abdominal wound was closed without drainage, intravenous glucose was administered, and the child was returned to bed in good condition without evidence of shock and with a pulse of 110 and a systolic blood pressure of 104.

Convalescence was uneventful, and the patient was discharged from the hospital 12 days after operation.

By September 28, 1939, he had gained 6 pounds, had returned to school, and there had been no complaints referable to the abdomen. The report of an x-ray examination by Dr. E. C. Vogt on this date was as follows:

A flat abdominal film shows the kidneys to be normal in size and position. There are no abnormal masses or calcification.

The barium enema fills the colon easily and well. The

\*Assistant in surgery, Harvard Medical School; associate surgeon, Children's Hospital.

colon is normal in contour, and it is in proper position. The cecum is rather low. There is no obstruction. Examination after evacuation shows complete emptying of the colon.

In a gastrointestinal series the esophagus appears normal. The stomach is medium in size and position and normal in contour and empties freely. The duodenum appears normal. Films taken at intervals up to 45 minutes very well delineate the small intestine which is normal in appearance. There are no obstructions or constrictions, and the position is normal. The mucosal pattern is well shown and entirely normal. The head of the biliary column at 45 minutes is at the hepatic flexure.

Impression: normal gastrointestinal tract.

On June 12, 1940, the patient entered the Children's Hospital (Boston). In the fall of 1939 he had complained of transient abdominal pain on several occasions. The pain was neither severe nor localized. He had been considered to have a good deal of gas. Otherwise he had been well and his schooling had not been interrupted. He was admitted to the hospital for abdominal exploration and closure of the aperture noted at the former operation.

On June 14, an operation was performed. Under ether and other anesthesia a transverse upper abdominal incision was made with division of both rectus muscles and the external oblique aponeurosis and retraction of the internal oblique muscle. This incision gave a very good exposure. The first abnormality encountered was a dense stringlike adhesion about 15 cm long running from the ileum to the transverse colon. This was ligated and divided. The inferior edge of the omentum presented as two layers that were not fused so that the omental bursa was open. The transverse colon and the omentum were displaced upward and the small bowel was packed away, exposing the root of the mesentery and the superior mesenteric vessels. Just below these vessels and directed upward to the right was a slitlike aperture approximately 2 cm in height. Through this aperture a No. 20 rubber catheter was easily passed for a distance of 15 to 20 cm. It went to the right and presented behind and lateral to the upper portion of the ascending colon just below the hepatic flexure. After this demonstration the catheter was withdrawn and the edges of the aperture described were roughened with gauze and then approximated with four interrupted fine silk sutures. Another adhesion running from a loop of ileum to the inferior end of the previous abdominal scar was divided. This adhesion was about 2 cm in width and was relatively vascular. The cecum was mobile and easily delivered and with it an extremely long but otherwise normal appendix. The mesoappendix was ligated and divided. The appendix was crushed at its base, ligated and removed with the cautery. The intestine was placed in normal position. The free edge of the omentum, which presented in two layers, was approximated by means of a series of interrupted sutures resulting in the closure of the omental bursa. The abdominal wound was closed in layers with out drainage. Interrupted black silk sutures were used throughout except for ligation of the appendiceal stump and for the peritoneal closure the latter being approximated by means of a continuous catgut suture. The patient was returned to bed in good condition.

Convalescence was entirely uneventful, and he was discharged on June 25.

He was seen on November 21, when he was in excellent health, had gained 8 pounds in the preceding 5 months and was actively engaged in schoolboy athletics.

Both wounds were solidly healed, and there had been no emphysema.

## DISCUSSION

The anatomic abnormality in this patient is explained embryologically by the imprisonment of the small intestine beneath the mesentery of the developing colon (Longacre<sup>1</sup>), and is not a hernia in the sense of the term that implies protrusion or evagination of the intestine from the celomic cavity. During the third stage of return of the intestinal tube from its temporary extrusion into the yolk sac—in the fifth to eleventh weeks of embryonic life—the mesocolon (in this case, the transverse mesocolon) may fail in part to fuse with the posteroparietal peritoneum. This affords opportunity for the midgut to be covered by or imprisoned behind the mesocolon and it is the mesocolon that presents the appearance of a covering or enveloping peritoneal sac.

Excellent clinical and anatomic descriptions are available in the recent American literature, and it appears unnecessary to reproduce them although it is desirable to refer to the sources. Historically, Neubauer<sup>2</sup> appears to have described the condition first; Treitz's<sup>3</sup> description in 1857 is classic, and the several allied conditions are often referred to as 'Treitz hernias,' since he believed that the intestine deepened and protruded into one of the several peritoneal fossas about the duodenum. Moynihan<sup>4</sup> published a monograph on the subject in 1906. Bender<sup>5</sup> suggested a developmental as opposed to an acquired mechanism, and Eisler and Fisher<sup>6</sup> and Bender<sup>6</sup> introduced the term mesentericoparietal hernia to replace Treitz and paraduodenal hernia (right and left) and to distinguish these anomalies from internal hernias, many of which bear no anatomic relation to the condition under discussion.

Two excellent papers, based on anatomic dissections,—one by Longacre<sup>1</sup> and one by Callander, Rusk, and Nemir,<sup>7</sup>—discuss the type of anomaly presented in the reported case. Both are fully and beautifully illustrated and serve to make clear the embryologic basis for a puzzling clinical picture. Longacre's bibliography is particularly complete. These papers, published respectively in 1934 and 1935, have been followed by numerous articles up to and including June, 1940.

Brynn<sup>8</sup> described the case of a nineteen-year-old girl treated successfully, and stated his to be the forty-third reported case of right paraduodenal hernia and the fifteenth patient to recover.

Emenheiser and Pankratz<sup>9</sup> reported on necropsy observations in a case of left paraduodenal hernia and Averbach<sup>10</sup> noted the successful treatment of a fourteen-year-old boy presenting findings very

similar to those of the patient reported in this paper.

Paul and Hill<sup>11</sup> commented on the autopsy findings in a three-month-old female and discussed the embryology from a viewpoint slightly different from those of the authors referred to above.

Halpert,<sup>12, 13</sup> in 1938 and 1939, reported post-mortem studies of a thirty-five-year-old woman with a right paraduodenal hernia and of a fifty-five-year-old man with a left-sided hernia, respectively. He states in the 1938 paper that he presents the forty-ninth confirmed case of right paraduodenal hernia.

Snyder<sup>14</sup> presented another case, not included by Halpert, of successful surgical reduction, but in this case, death followed forty-eight hours after operation. The patient was a man of fifty-one with extensive pulmonary tuberculosis.

Johns<sup>15</sup> reported a left transmesocolic hernia and emphasized the importance of a significant symptom—the pain, however severe when standing, is relieved when the patient lies down. His patient was a man of twenty-eight years.

Hansmann and Morton<sup>16</sup> presented the case of a fifty-eight-year-old cretin whose hernia occurred through the external leaf of the mesentery of the ascending colon, and reproduced the roentgenograms, with and without barium, after the cecum had become obstructed. These authors review the subject and give a bibliography but include hernias that were sequelae of abdominal operations involving the several mesenteries. They make the valuable observation, based on statistics, "that in most instances the stoma of intra-abdominal hernia will be found by lifting up the transverse mesocolon and exploring the paraduodenal region."

Developmentally the condition described is intimately related to and may present symptomatology similar to the extrinsic obstructions stressed by Ladd.<sup>17-21</sup> In these obstructions, owing to incomplete rotation of the colon and defective mesenteric development, there may be a volvulus of the small intestine and compression of the duodenum by the overlying and abnormally placed cecum and ascending colon. Haymond and Dragstedt<sup>22</sup> have also described anomalies of intestinal rotation.

For references to imprisonment of segments of the small intestine in apertures in the paracecal ascending colon, there are articles by Chamberlain<sup>23</sup> and by Cullen.<sup>24</sup> A third case (C. H. No. 223661), not reported but successfully treated by resection of part of the ileum, was operated on by Dr. T. W. Botsford at the Children's Hospital in August, 1939.

The patient reported here differs from others previously mentioned because the imprisonment

was by the transverse mesocolon rather than by the ascending or descending mesocolon, because volvulus of the small intestine was present, and because the terminal ileum, cecum and part of the ascending colon were imprisoned, as well as the jejunum and upper ileum, which have been reported before. These are not discrepancies, however, since in addition to either the ascending or the descending mesocolon, the transverse colon may fail to fuse to the posterior peritoneum. Furthermore, all the imprisoned bowel was, embryologically speaking, part of the midgut—that is, the part supplied by the superior mesenteric artery. The presence of volvulus of the small intestine is quite uniformly found in the anomalies described by Ladd.<sup>17-21</sup>

Longacre<sup>1</sup> summarized the evidence for the belief that such cases are congenital anomalies by pointing out the size and extent of the so-called "sacs," the absence of a definite neck, the absence of entering and departing loops, the absence of omentum in the sacs, and peculiarities in the blood supply that cannot be explained as acquired. In the present case the exigencies of operation prevented observation of anomalies of blood supply, but to Longacre's evidence may be added the imprisonment of essentially all segments of the intestine arising from the midgut, the defective mesenteric attachments and the volvulus, which also occurred in the undoubtedly congenital anomalies described by Ladd.

Clinically the condition, although rare, bears an intimate relation to other forms of intestinal malrotation and reverse rotation that may produce obstructive phenomena in the newborn or later in life. It may also be the cause of symptoms similar to those produced by internal herniations into apertures in the broad ligament and omentum, and by incarceration of knuckles of bowel into the several pericecal and paraduodenal fossas.

It appears from the data reported that cases of this type are congenital anomalies of development of the intestinal tract, that they may exist without producing functional disturbance, that they may be responsible for long-continued but vague symptoms of disturbed intestinal function, and that they may produce acute obstruction phenomena, with varying degrees of circulatory impairment of the bowel. Andrews<sup>25</sup> states that the treatment of strangulation appears to be almost hopeless, reduction being nearly 100 per cent unsuccessful. He adds that unless strangulation takes place, the bowels are able to function normally.

About 50 cases of so-called "herniation" into the right mesocolon have been reported, about 150 into the left, and 2 into the paracecal segment of

the right colon; the present case is considered to be imprisonment by the transverse mesocolon.

Correct preoperative diagnosis is seldom possible, a total of 5 having been reported by Abrazon, von Haberer, Vautrin and Slandenmeyer (Longacre<sup>1</sup>). The use of x-ray examination has been suggested, and Snyder's<sup>14</sup> patient did present an appearance suggestive of incarceration of many loops of intestine. The existence of a tympanitic circumscribed mass has been described, but apparently has not been found in most cases. The usual symptoms are those of intestinal obstruction with varying degrees of shock. Pain appears to be the most constant symptom, and together with abdominal tenderness, may be the indication for operation. In this connection, one can do no better than to quote with Chamberlain<sup>23</sup> the statement of Mason and Atkinson<sup>26</sup>. "Time spent in differential diagnosis is ill spent. The decision to be made is whether or not the condition is surgical. The chagrin of the surgeon who operates and fails to find a surgical condition is nothing to that of the surgeon who does not operate in time."

Successful treatment postulates early operation before serious circulatory disturbances have developed, and a reasonably accurate knowledge of embryologic development so that a rational plan for relieving the intestinal obstruction and the vascular obstruction may be employed.

#### SUMMARY

A case of imprisonment of the segments of the intestine arising from the midgut by a congenital anomaly of the transverse mesocolon is presented, it is believed, for the first time; the successful surgical management of the patient is described.

The embryologic explanation for the anomaly is briefly described, and references are given to the descriptions of the related anomalies of so-called "herniations" into or imprisonment by the ascending and descending mesocolons. The clinical

and anatomic relations to other forms of faulty rotation and attachment of the colon are discussed. Additional evidence for the developmental basis for such anomalies is added—namely, the imprisonment of essentially all the intestine arising from the midgut, the defective mesenteric attachments and the coexistent volvulus of the small intestine. The designation of "hernia" is retained, since it is a useful and convenient term, although the anomaly is not a hernia in the usual sense.

1101 Beacon Street

## GALLSTONES IN PATIENTS UNDER THIRTY YEARS OF AGE

CARL BEARSE, M.D.\*

BOSTON

ALTHOUGH approximately 10 per cent of the population have gallstones,<sup>1</sup> the prevalence of this condition in patients beyond forty years of age has obscured its relative frequency in young persons. An analysis of 300 consecutive cases of operation for gall-bladder disease, including non-calculous cholecystitis,<sup>2</sup> disclosed that 21 per cent of the patients were under thirty years of age. It has been suggested<sup>3</sup> that if routine cholecystography were carried out in young persons, biliary-tract disease would be found even oftener.

In the present study of 232 unselected patients operated on for gallstones, 48, or 20 per cent, were under thirty years of age. There were 3 males and 45 females. The males were in their third decade, as were 41 of the females. The remaining 4 females were operated on before their twentieth year, the youngest being fourteen years of age.

Previous acute infections, including the exanthematous diseases, have been suggested as etiologic factors in the formation of gallstones in young persons. Twenty-seven patients (56 per cent) gave a history of one or more of these infections. Measles was the commonest, and whooping cough and scarlet fever were next in frequency. There were several cases of typhoid fever, chicken pox and mumps, 1 of smallpox and malaria, and 1 of influenza.

More than 50 per cent of all patients with gallstones have been reported to be obese,<sup>4-6</sup> but only 21 per cent of these young patients were overweight; 11 per cent were thin, and 68 per cent were of normal weight.

The symptoms were no different from those in other age groups. Although all these patients had pain to some degree, only 18, or 38 per cent, at times required morphine by hypodermic injection. In comparison with reports for older patients, nausea and vomiting (in 40 per cent) were approximately as frequent, but eructations (in 18 per cent) were about one fourth as common. In 6 patients (13 per cent) jaundice was present at the time of operation or had been observed during previous attacks.

The duration of symptoms varied from one day to seven and a half years (Table 1). The average was one year and eleven months, approxi-

mately four years less than the average for patients of all ages.<sup>7, 8</sup>

Approximately 70 to 90 per cent of women operated on for gallstones have symptoms in relation to pregnancy<sup>9</sup>; of the 36 married women in this

TABLE 1. *Duration of Symptoms.*

DURATION	NO. OF CASES
Less than 1 yr	15
1 to 2 yr	11
2 to 5 yr	17
Over 5 yr.	4
Unknown	1
Total	48

series, 18 (50 per cent) had attacks during the gravid state. The frequency of attacks during and shortly after gestation has been attributed to hypercholesterolemia, impairment of gall-bladder function and constipation. One patient, aged twenty-eight years, had attacks of pain so severe that the gall bladder was removed during the fourth month of pregnancy. She had an uneventful convalescence and no further symptoms during or subsequent to her pregnancy and confinement.

Six patients (13 per cent) had acute cholecystitis in addition to cholelithiasis. Four had symptoms for two months or less; the remaining 2, one and a half and seven and a half years, respectively. The gall bladders were viable, although in 1 case the mucosa was gangrenous. The fact that the symptoms did not exceed eight weeks in 4 of these patients indicates that acute cholecystitis in young persons may occur early during the course of cholelithiasis.

The common duct was opened and explored in 8 cases; stones were found in 3, an incidence of only 6 per cent for the series. These patients, whose ages were between twenty-four and twenty-seven years, had symptoms from four to seven years; none were jaundiced at the time of operation, and only 1 gave a history of jaundice. As in older patients, the longer the duration of symptoms, the greater the incidence of this complication.<sup>10</sup> For patients of unselected ages, 16 to 21 per cent are estimated to have choledocholithiasis,<sup>11, 12</sup> with jaundice in 60 to 91 per cent.<sup>12, 13</sup>

Three patients (6 per cent), who were twenty-six, twenty-seven and twenty-nine years of age, respectively, had acute pancreatitis in addition to

\*Associate visiting surgeon, Beth Israel Hospital.

cholelithiasis. One had edema of the pancreas, and the other 2 had hemorrhagic pancreatitis with fat necrosis. One was operated on within twenty-four hours of the onset of the first gallstone attack, and the others had biliary symptoms for one and three years, respectively. It is therefore obvious that young patients with gallstones can have acute pancreatitis as an early complication.

There were no deaths in the series. The gall bladder was removed in each case, and, as already mentioned, the common duct was opened and explored in 8. Thirty-eight patients (79 per cent) also had an appendectomy, including 7 who had additional surgery.

Forty-six patients (96 per cent) had an uneventful convalescence and were discharged from the hospital within two weeks of operation. One of the remaining patients was in the hospital thirty-five days because of a phlebitis, first of one leg and then of the other. The second patient, whose common duct was drained, had a nonvirulent gas-bacillus infection necessitating twenty-one days of hospitalization.

It has been possible to follow 38 patients (79 per cent) for a period of one to fourteen years. Only 2 have thus far complained of subsequent distress. One patient had epigastric discomfort two years postoperatively; roentgen-ray examination revealed a duodenal ulcer. The other, after being free from symptoms for four years, had an attack of epigastric pain that persisted for several days. Careful investigation, including a gastrointestinal roentgen-ray examination, was negative. Whether the recurrence of pain in this patient was due to an overlooked common-duct stone or to an extrabiliary condition has not yet been determined. The 3 patients who had stones removed from the common duct have been free from symptoms for two to four years.

## SUMMARY

Of 232 consecutive operations for cholelithiasis, 48 (20 per cent) were on patients under thirty years of age. The average duration of symptoms was one year and eleven months.

In addition to cholelithiasis, 6 patients (13 per cent) had acute cholecystitis, 3 (6 per cent) had acute pancreatitis, and 3 (6 per cent) had stones in the common duct.

The gall bladder was removed in each case. There were no deaths, and postoperative complications occurred in only 2 patients.

Of the 38 patients (79 per cent) who have been followed for more than one year only 1 developed symptoms that might have been related to the biliary tract, and these occurred four years after operation. There has been no recurrence of symptoms in those who had common-duct stones.

483 Beacon Street

# MASSACHUSETTS MEDICAL SOCIETY

## PROCEEDINGS OF THE ONE HUNDRED AND SIXTIETH ANNIVERSARY

THE one hundred and sixtieth anniversary of the Massachusetts Medical Society was observed in Boston on Wednesday and Thursday, May 21 and 22, 1941, at The Copley-Plaza.

### WEDNESDAY, MAY 21

A general clinical meeting was held in the Sheraton Room in the forenoon, under the chairmanship of Dr. Bennett F. Avery. The attendance was approximately 425.

The supervising censors met in Parlor A at 10:00 a.m., and the Council convened in the Swiss Room at 10:30 a.m., the Cotting Luncheon being served at 1:00 p.m.

During the noon hour, the sections met for a series of round-table discussions and luncheons, at which the new officers were elected. The Section of Medicine met at the University Club, with an attendance of 148; the Section of Obstetrics and Gynecology at the University Club, with an attendance of 77; the Section of Surgery in the State Salon of The Copley-Plaza, with an attendance of 85; the Section of Pediatrics at the Hotel Lenox, with an attendance of 56; the Section of Dermatology and Syphilology at the Hotel Lenox, with an attendance of 53; the Section of Radiology and Physiotherapy at the Hotel Lenox, with an attendance of 13; and the Massachusetts members of the New England Society of Anesthesiology at The Copley-Plaza, with an attendance of 35.

In the afternoon, a general clinical meeting was held in the Sheraton Room, Dr. C. Sidney Burwell presiding. The attendance was around 450.

That evening, the annual dinner was held in the Sheraton Room, 281 members and guests being present. The president, Dr. Walter G. Phippen, introduced the delegates from the medical societies of the other New England states, as follows:

MAINE: Dr. Theodore E. Hardy, Waterville

NEW HAMPSHIRE: Dr. Clinton R. Mullins, Concord  
Dr. Leslie B. Copenhaver, North Woodstock

VERMONT: Dr. Michael F. Cerasoli, Barre

RHODE ISLAND: Dr. Charles A. McDonald, Providence  
Dr. Joseph C. O'Connell, Providence

CONNECTICUT: Dr. Charles H. Turkington, Litchfield

Dr. F. Erwin Tracy, Middletown

After short speeches by Drs. Nathan B. Van Etten and Frank H. Lahey, president and president-elect, respectively, of the American Medical Association, the attending fellows adjourned to the Swiss Room, where Dr. E. W. Alton Ochsner, of New Orleans, delivered the Shattuck Lecture, his subject being "Thrombosis and Thrombophlebitis." (This lecture will appear in the July 31 issue of the *Journal*.)

### THURSDAY, MAY 22

A symposium on hormones was held during the early forenoon, under the chairmanship of Dr. Charles E. Mongan; the attendance was approximately 425.

### ANNUAL MEETING

The one hundred and sixtieth annual meeting was called to order by the president, Dr. Walter G. Phippen, in the Sheraton Room at 11:00 a.m. Approximately 400 were in attendance. The minutes of the previous annual meeting were approved as published in the July 4, 1940, issue of the *New England Journal of Medicine*. The Secretary *pro tempore* then presented the changes in membership, as follows:

Membership reported May 22, 1940 ..... 5542

#### Losses

Deaths	104	
Resignations	17	
Deprivations	49	
	—	170

#### Gains

Readmitted by censors	1	
Restored by Council	28	
	—	267

Net gain . . . . . 97

Membership reported May 22, 1941 . . . . . 5639

Proposed changes in the by-laws, which had previously been approved by the Council and copies of which had been forwarded to all members of the Society, were then considered. Dr. Phippen called attention to the fact that the last

four proposed amendments had been inadvertently omitted from the notice of the annual meeting and that a postcard calling attention to the omission had been sent to every member. The amendments were considered in order, and were accepted without change, except that in Amendment 17 the word "Society" in the next to the last line in the first paragraph was changed to "Council". The amendments, as accepted, were as follows:

**AMENDMENT 1** Amend Chapter I, Section 1, to read

Applicants for admission to fellowship in the Massachusetts Medical Society are required to satisfy the censors that they are not less than twenty-one years of age, that they are of sound mind and of good moral character, that they possess a good English education, that they have received a diploma from a medical school or college recognized by the Council, or that they have, in each instance, received the approval of the Committee on Medical Education, that they do not practice medicine in a manner contrary to the code of ethics of this society, that they have made application according to the provisions of Chapter V, Section 2, that they have paid the examination fee of three dollars and they shall appear personally before the censors and satisfy them that the above requirements are fulfilled.

**AMENDMENT 2** Amend Chapter I, Section 6, to read

Fellows shall be assessed annually such a sum as the Council may determine. The fiscal year shall begin on the first day of January. Assessments shall be payable in advance. The first assessment paid by a fellow admitted to the Society following the December examinations shall cover his dues for the succeeding fiscal year and shall be the amount fixed for that year.

**AMENDMENT 3** Amend Chapter I, Section 7, to read

The resignations of fellows whose assessments have been paid in full or remitted, may, on recommendation of the Committee on Membership, be accepted by the Council. Petitions to be allowed to resign should be sent to the treasurer of the general society.

**AMENDMENT 4** Omit the last paragraph of Chapter I, Section 9.

**AMENDMENT 5** Add in Chapter I the following

**Section 10** Former fellows who desire to be re-admitted to the Society shall make application in writing addressed to the Council and sent to the secretary of the Society. Such applications shall be referred for investigation and personal interview to the local boards of membership, which shall report their recommendations to the Committee on Membership. The committee shall render the final decision as to whether to recommend to the Council the readmission of former fellows. The Council shall have the power to readmit former fellows so recommended. Boards having under consideration the applications of fellows whose resignations have been requested by the Committee on Ethics and Discipline, or who have been deprived of fellowship under the terms of Section 8, Clause (c), shall consult with the Committee on Ethics and Discipline before reporting their recommendations.

**AMENDMENT 6** Add to Chapter III, Section 5, the following

The councilors of each district society shall meet at or as soon as possible after the annual meeting of the district society in 1941 and elect one of their number to serve as a member of the Executive Committee of the Council, in accordance with Chapter IV, Section 10. Thereafter, in a similar manner, they shall elect a new member from time to time.

**AMENDMENT 7** Add in Chapter III, Section 7, the following

The secretary of each district society at or as soon as possible after the annual meeting of the district society and before the annual meeting of the general society in 1941 shall call together its councilors for the purpose of electing a member of the Executive Committee of the Council and shall send the name of the member chosen to the secretary of the general society. He shall see that a new member is chosen in a similar manner to fill a vacancy as it occurs, in accordance with Chapter IV, Section 10.

**AMENDMENT 8** Add to Chapter IV the following

**Section 10** The Executive Committee shall consist of the President, President Elect, Vice President, Secretary and Treasurer *ex officio*, and a councilor from each district medical society chosen in accordance with Chapter III, Section 5.

The councilors of each district society shall meet at or as soon as possible after its annual meeting in 1941 as specified in Chapter III, Section 5, and in a similar manner at stated intervals as specified below, to choose one of their number to serve as a member of the Executive Committee of the Council.

A member of the Executive Committee shall serve for three years and shall not be eligible for re-election before the expiration of three years following the conclusion of his term of office except that in the first year of operation six members shall be selected by lot to serve one year, six members shall be selected by lot to serve two years and six members shall be selected by lot to serve three years. Thereafter six members shall be elected every year to succeed in office those whose terms are about to expire.

The Executive Committee shall meet at the call of the President at least once in each interval between Council meetings and may meet more often at the pleasure of the President. It shall assist the President in preparing for the consideration of the Council matters calling for action by the Council at its next meeting. It shall authorize action by the officers of the Society when circumstances require it subject to the approval of the Council. It shall perform such other duties as the Council may require.

An executive secretary may be chosen by the Executive Committee upon nomination by the President.

Upon request members of the Executive Committee shall be paid the amount of their traveling expenses from the funds of the Society.

**AMENDMENT 9** Amend Chapter V, Section 1, to read

The supervisors representing the censors of the several district societies, shall constitute a board which shall meet annually on the day appointed for the annual meeting of the Council. The board shall elect a chairman, who shall have power to call special meetings. Five supervisors shall constitute a quorum. The secretary or executive secretary of the general society

shall act as secretary of the board. He shall call special meetings at the request of five supervisors. He shall keep a permanent record of the proceedings of the board, and shall provide, at the expense of the Society, papers and forms necessary for conducting examinations of applicants for fellowship. The board at its annual meeting shall adopt a uniform plan for the examination of applicants. The supervisors shall be paid the amount of their traveling expenses from the funds of the Society.

The supervisors shall be chairmen of their respective boards of censors, and shall cause the examinations of applicants to be conducted in strict conformity to the plan adopted by the Board of Supervisors.

The censors of the several district societies shall meet semi-annually for the examination of applicants on the first Thursday in May and on the first Thursday in December.

A fee of three dollars shall be paid to the district secretary by an applicant for fellowship for each examination or re-examination by the censors. This shall be sent promptly to the treasurer of the general society for deposit in the funds of the Society. An applicant shall not be considered as possessing the requisite qualifications for fellowship unless approved by at least three censors. An applicant failing two examinations shall be disqualified from again applying for fellowship until three years have elapsed from the date of the last application.

AMENDMENT 10. Change Chapter V, Section 2, to read:

(a) An applicant for fellowship who is a graduate of a medical school or college recognized by the Council shall apply on a form furnished for the purpose to the secretary of the district in which he has legal residence not later than February 15 for the May censors' examination or September 15 for the December censors' examination. At this time the district secretary shall verify the applicant's diploma and shall deliver the application form to the secretary of the general society not later than February 20 or September 20 respectively. An applicant nonresident in Massachusetts shall apply to the secretary of the Suffolk District Medical Society and shall be examined by the censors thereof. Consideration of a late application shall be postponed until before the next succeeding examination. The names of all such applicants, their addresses, medical schools and colleges, dates of graduation and the names and addresses of the various district secretaries shall be published in a list in the first number of the *New England Journal of Medicine* on or after March 5 or October 5. Confidential communications regarding the qualifications of applicants for fellowship shall be requested of the fellows of the Society to be sent to the appropriate district secretary not later than March 15 or October 15.

(b) An applicant for fellowship who is a graduate of a foreign medical school or college or a domestic medical school or college not on the list recognized by the Council or of a medical school or college no longer in existence, and who has practiced for a minimum of five years, shall apply for fellowship in like manner with the following exceptions and additions:

At the time of application the applicant must submit the name and address of a fellow of the Society who has agreed to act as his sponsor. The sponsor's duty is to obtain from fellows of the Society who are acquainted with the applicant and his work, confidential written opinions regarding his qualifications

for fellowship to be mailed directly to the district secretary not later than March 15 or October 15. The list of these applicants published in the *New England Journal of Medicine* shall also include the names and addresses of the applicants' sponsors.

The president, secretary and supervising censor of the district society, sitting as a local board of membership, shall then gather such further information as is deemed necessary to determine whether an applicant is a capable and conscientious practitioner of medicine and possesses a good professional reputation among his colleagues. Every candidate must be personally interviewed by this board.

The district secretary shall deliver to the chairman of the Committee on Medical Education a complete confidential file of all applications including correspondence, and the written recommendations of the local board with supporting reasons for advocating the acceptance or refusal of each applicant not later than April 1 or November 1. The Committee on Medical Education shall then determine whether or not each candidate shall be approved for examination by the censors, and shall notify the district secretary and each applicant of its decision not later than April 20 or November 20.

AMENDMENT 11. Amend Chapter V, Section 3, to read:

District secretaries, who shall act as secretaries of their respective boards of censors, shall furnish applicants with forms adopted by the Board of Supervisors; they shall keep a complete record of all applicants for fellowship; they shall see that each applicant pays the examination fee; . . .

AMENDMENT 12. Add to Chapter VI, Section 1, the following:

He shall call at least one meeting of the Executive Committee of the Council between Council meetings, and may call more meetings if he so desires.

AMENDMENT 13. Change Chapter VI, Section 3, to read:

The Secretary may assign to an executive secretary any or all the duties now to be enumerated, except as specified below:

The Secretary shall attend all meetings of the Society and of the Council, and shall record their respective proceedings in separate record books; and this duty he may not assign.

He shall cause to be engrossed and shall sign the diplomas of new fellows if satisfied that they have met the requirements of Sections 1 and 2 of Chapter I, and shall issue all diplomas and certificates of fellowship. He shall notify individual fellows, in appropriate instances, of votes by the Council granting permission, as the case may be, to retire, to resign, to change district membership, to have dues remitted, or of votes depriving them of the privileges of fellowship; and these duties he may not assign.

He shall act *ex officio* as secretary of all boards of trial; and this duty he may not assign.

He shall have custody of the seal of the Society and of all books, papers, manuscripts, prints and paintings belonging to the Society, except such as are in charge of the Treasurer; and this duty he may not assign.

He shall act *ex officio* as secretary of the Board of Supervisors and of the Committee on Publications and the Committee on Ethics and Discipline, and shall keep the records of each in a separate volume. He shall have custody of all records as thus kept.

He shall issue notices of the meetings of the Council. One month before the annual meeting of the Society, he shall issue to every fellow a program which shall contain notification of the time and place of the annual meeting, notification of the stated meetings of the Council for the year and the meetings of the boards of censors, and information concerning the payment of assessments and the distribution of publications.

He shall keep a complete list of the fellows of the Society, with their addresses so far as known. He shall transfer fellows from one district to another under the terms of Chapter III Section 2, and shall report to the Society at its annual meeting the changes in membership of the Society during the year.

He shall conduct the official correspondence of the Society and shall notify officers, delegates and members of the committees of the Society of their appointments and of their duties.

Under the direction of the Committee on Publications he shall issue at such intervals as may be determined by the Council a directory of officers and fellows of the Society, which shall be furnished upon request to fellows who are not in arrears.

He shall perform such other duties as the Society or the Council may require.

#### AMENDMENT 14 Change Chapter VI, Section 5 to read

The Executive Secretary shall hold office at the pleasure of the Executive Committee of the Council.

He shall perform such duties as are assigned to him in Section 4 of this chapter and by the Executive Committee. In general he shall assist the officers of the Society and such standing and other committees as may request his services and the Society shall have the first call upon his services.

He shall attend all meetings of the Council and no request attend the meetings of the Executive Committee of the Council, but shall not vote in either.

The Executive Secretary need not be a physician.

#### AMENDMENT 15 Amend Chapter VII, Section 5, to read

The Committee on Medical Education shall consist of five fellows. It shall consider all matters relating to medical education which may be referred to it by the Council. It shall review the case of every applicant for fellowship who presents a diploma according to the provisions of Chapter V, Section 2(b). It shall have the power to approve for examination by the censors such an applicant and all decisions of the committee thereon shall be final. It shall revise the list of medical schools and colleges recognized by the Council annually for approval by the Council.

#### AMENDMENT 16 Amend the first paragraph of Chapter IV Section 1, to read

The Council shall consist of councilors chosen by the district societies and the president, ex-presidents, president elect, vice president, vice presidents *ex officio*, secretary and treasurer of the general society, secretaries of the district societies and the chairman of each standing committee.

#### AMENDMENT 17 Amend the first paragraph of Chapter IV Section 3 to read

The Council at its annual meeting on nomination by the Nominating Committee and/or from the floor shall elect by ballot officers of the Society as follows: president elect who shall serve as president elect until

the annual meeting of the Society next ensuing after his election and shall become president on his installation in the course of that meeting serving thereafter as president until the next following annual meeting and the installation of his successor a vice president, secretary and treasurer, all of whom shall assume the duties of office at the close of the annual meeting of the Society and shall hold office until their successors have been duly elected except only that at the annual meeting of the Council in 1941 there shall be nominated and elected a president to serve for that year.

In the absence of a president elect the Council at its next annual meeting shall upon nomination by the Nominating Committee and/or from the floor elect a president. Councilors only shall be eligible to the offices above named. Upon nomination by the Nominating Committee the Council shall elect by ballot a fellow to deliver an oration at the annual meeting of the Society the following year.

#### AMENDMENT 18 Change Chapter VI Section 3 to read

The President Elect shall assist the President in the performance of his duties in such a manner as the President may direct and in so doing shall be considered to represent the President.

#### AMENDMENT 19 Change Sections 3, 4 and 5 Chapter VI to Sections 4, 5 and 7 respectively

Dr Leroy E. Perkins moved that a vote of thanks be extended to the Committee of Arrangements for the very excellent program that had been presented, the motion was seconded and carried.

Dr Phippen then gave his report on the state of the Society.

It is my duty at this time to report on the state of your society. It is a pleasure to say that it continues to grow and prosper. Its activities are expanding. Its influence is beginning to be felt. A larger proportion of members are giving more thought to the affairs of the parent society. The attendance at Council meetings has been very gratifying and denotes I believe a more careful selection of councilors by the district societies. Only men who are willing and able to give freely of their time and thought should be elected to these important positions.

The total membership now numbers 5639 an increase of 97 in the past year.

The Society sustained a great loss during the year to the death of its very able secretary Dr. Alexander S. Begg. Dr. Begg was devoted to the interests of the Massachusetts Medical Society. He knew its history and its traditions. He probably knew more members intimately than any other member. Moreover he was a keen judge of men and knew who could be entrusted to do any particular job well. We miss him sadly but in so doing rejoice in his acquaintance and do honor to his service.

Our able and devoted treasurer reports again that our finances are as sound as the times will allow. He has continued his policy of placing funds of the Society in bonds and in most cases only in the best. One result of this is lower interest rate but with greater security of principal. At present the Society has a large amount of cash awaiting investment owing mainly to the receipt of 1941 dues. The Treasurer has not been able to invest

all in securities fit, in his opinion, for our funds. Almost all the Society's holdings of bonds are well above the cost prices. The Society, so far in 1941, has received from securities sold or from securities called for early payment a profit of several hundred dollars. No default in interest receivable has occurred this year, other than the issues already in default for several years. Collections of annual dues from resident fellows, to May 1, are greater than in 1940 for the same period. Nonresident dues received are also greater than in 1940. Expenses through April, 1941, have shown increases, but not to an unreasonable degree.

The Treasurer regrets that he feels obliged to carry such a large amount of cash awaiting investment. This idle cash should be earning income for the Society. The Treasurer is seeking, and occasionally finding, what he thinks is a proper medium for our funds.

A goodly number of fellows of the Society have been called to active duty with the United States Army and Navy. Some of these have asked to have their 1941 dues remitted.

Again I congratulate the Society on the wisdom and sagacity of its treasurer, and again I thank the Treasurer in the name of the Society for his conscientious and able service.

The standing committees have continued their efficient work.

It is a pleasure to note that the Committee on Ethics and Discipline has had rather less troublesome problems. We hope this is a good augury.

The Committee on Postgraduate Instruction conducted a very successful assembly for the third successive year. Again rain interfered, and it is planned to hold the Assembly earlier this year in the hope of better weather. The papers were excellent, and the question-and-answer period at luncheon was particularly worth while. The district courses have been continued, but the attendance at some might have been better.

The Committee on State and National Legislation has had a busy year. The major portion of its work is over, however, for with the exception of the annual-registration bill, the various premarital blood-test bills, the nurses' bill and some recently entered bills dealing largely with defense, the final reports are in.

Not every bill we favored was passed, nor was every bill we opposed turned down; but the important ones have gone our way, or at least have been put over for another two years. The Chiropractic Bill was beaten, and the Osteopathic Bill was withdrawn by the proposers, as was the bill to study the practice of surgery. The two bills to postpone and nullify the operation of the Approving Authority were given leave to withdraw.

Along with the Committee on Public Relations, and the Special Committee, the committee has spent a great deal of time and effort guiding our own enabling act through the Legislature. It was favorably reported by the Committee on Insurance and the Committee on Ways and Means, it passed the House, and yesterday it was passed by the Senate.

The hearings before the Committees were well attended, and I take this occasion to express the thanks of the Society to those members who gave their time to this duty.

I also thank the district chairmen for their splendid co-operation in the work of the Committee on State and National Legislation, and particularly the members of the Legislature, who gave the bill so much thought and so patiently listened to our arguments.

I am sure you all appreciate the time-consuming, ex-

acting work that Dr. Lanman and his committee have given to this problem. Much now remains to be done to set up the organization, and it cannot be done without your hearty co-operation.

The *Journal* has continued to improve in quality and in circulation. It is interesting to note that there has been an increase of over 1000 outside subscribers—that is, nonmembers of the Massachusetts Medical Society—in the last two years. Sixty-eight per cent of the papers presented to the editorial board were accepted, an increase of 6 per cent over the preceding year. The operating loss of \$20,438 is covered by your contributions to the *Journal*, which this year totaled \$20,500. I am sure we have every reason to be proud of the *Journal* and its very efficient editor.

I take this occasion to thank the editor for his willingness to undertake the additional duties of secretary *pro tempore*, a service that I am sure you all join with me in appreciating.

The Council, after thorough deliberation and debate, has recommended very comprehensive changes in the by-laws, which you have today approved. The setting up of the office of president-elect will, I believe, be of great benefit, in that it offers a year of apprenticeship, so to speak. The president will come into office with a far better knowledge of the Society and its component parts than is at present possible. The Executive Committee of the Council will prove to be a more and more useful piece of machinery as time goes on. Composed of one member from every district society it will be a truly representative body. The president has to decide many questions which arise between meetings of the Council that might better be referred to a representative body such as the Executive Committee will be. The by-laws now allow the appointment by the Executive Committee of an executive secretary, if and when the affairs of the Society seem to require such a full-time officer.

It seems to me that the time has come when the headquarters of the Society should assume a certain amount of dignity. It should offer hospitality to visitors and a wholesome welcome to our members. Here should be found daily lists of clinics and meetings. It should be modeled, perhaps, something like the Academy of Medicine in New York City, manned by a competent staff and open daily throughout the week. This might mean some structural rearrangement, but I believe it could be accomplished and in the doing add to the prestige of the Society. A full-time executive secretary would amplify this scheme. I commend it to your earnest consideration.

The changes in the by-laws relating to the admission of members deserve your careful reading. The requirements for admission to fellowship by an applicant who is a graduate of a foreign or substandard domestic medical school have been greatly strengthened. In the first place he must submit the name of a fellow who agrees to be his sponsor. In the second place a local board of membership is set up in each district consisting of the president, secretary and supervising censor, who must personally interview the applicant, weigh the evidence, form an opinion and report it to the Committee on Medical Education. This committee shall then decide whether the candidate shall be examined by the censors.

The machinery for the readmission of members has been somewhat simplified and at the same time strengthened. The time-consuming method of appointing special committees to consider applications for reinstatement has been abolished and the responsibility placed in the hands of a membership committee of each district society, whereas

the ultimate authority to recommend still resides in the Committee on Membership, and the Council, as heretofore, alone has power to readmit. The thanks of the Society are due to the members of the Committee on Medical Education for their very thorough work.

Your society has taken an active part in the preparedness program. Your members have responded loyally to serve on draft, advisory and appeal boards, giving generously of their time and strength without thought of compensation. The State Committee, headed by Dr. Fitz, through the district committees has helped to round up delinquent questionnaires. It has given such aid as it could to the Army-Corps surgeons and stands ready to render more when required. It co-operated with the three medical schools of Boston in sponsoring a meeting of the draft board and appeal board chairmen in an effort to persuade them that the education of medical students must not be interrupted until at least one year of internship shall have been completed and to urge them to defer medical students for this period. It is gratifying to note that the Selective Service Board has finally decreed that this is a proper procedure, provided each case is acted on individually, and that the student gives fair promise of becoming a reasonably good doctor.

Last June the Surgeon General of the Army proposed to the House of Delegates of the American Medical Association that they set up a committee to aid in the procurement of medical officers, recognizing that in the event of a national emergency it would be very necessary to conserve the medical profession and prevent the stripping of rural and isolated communities. This committee has been actively at work since then. Among other things we were asked to help in providing specialists for the various 1000 bed hospitals in the newly constructed camps. Lists of such available specialists were assembled and sent to the various Army-Corps surgeons within a short time. The General Staff, however, ordered that these specialists should be taken only from the Medical Reserve Officers Corps. The General Staff further decreed that no doctor should be newly commissioned in the Reserve Officers Corps above the rank of first lieutenant. It is therefore impossible for the Corps Area surgeons to obtain all the specialists they desire. It is hoped that some way may be found to utilize available and willing specialists and to give them a rank of captain or major, commensurate with the position and authority.

The Army estimates that its reserve corps will be exhausted by the middle of summer. It also estimates that it will need a yearly turnover of something like 9000 doctors. It seems wise at present that any unmarried doctor within the draft age should apply for a reserve officer's commission, rather than be drafted to an uncertain assignment. What lies ahead of us no one knows. We do know that the United States Army, Navy and Public Health Service need many doctors, and at the same time civilian needs must not be overlooked.

In closing I thank all the officers and committees for their untiring efforts and ready responses to my calls. Their loyalty and support have meant much to me in these somewhat trying two years.

It is difficult to find words to express to you, as members of this oldest medical society in America, my thanks for the high honor you have done me.

Dr. Phippen then introduced the orator, Dr. A. Warren Stearns, who delivered the Annual Discourse, "The Role of the Physician in a Competitive Society" (published in the May 22, 1941, issue of the *New England Journal of Medicine*).

Dr. Frank R. Ober, president for the ensuing year, was introduced and made a few remarks. The meeting was adjourned at 12 35 p.m.

Following the annual luncheon in the Swiss Room, a military symposium was held in the Sheraton Room, Dr. Dwight O'Hara presiding; the attendance was at least 500.

\* \* \*

There were twenty-two scientific and sixty-three technical exhibits, all of which were extremely well attended. The motion picture program, which covered both days, was so popular that sufficient seating capacity was not available.

The Ladies' Committee arranged an attractive program. On May 21, after a visit in the afternoon to the Isabella Stewart Gardner Museum, there was a dinner at the Roof Garden, Hotel Ritz-Carlton. A trip to the South Shore was made on May 22, including visits to the Dorothy Quincy House and Adams Mansion in Quincy and to the Cushing Homestead and Old Ship Church in Hingham, with luncheon at Hugo's in Scituate.

The annual golf tournament was held at the Commonwealth Country Club on May 21. Forty-two members participated, and the winners were as follows:

Low net (Burrage Bowl) — A. J. A. Campbell  
Second low net — H. E. Groden  
Third low net — L. F. Phylse  
Low gross — E. E. O'Neil  
Second low gross — Mirgan Sargent  
Third low gross — T. E. Dinan

The total registration was as follows.

Members and guest physicians	1525
Ladies	175
Total	1700

The lists of admissions and deaths are appended, together with the official lists of officers, standing and special committees, delegates, councilors, censors, section officers and officers of the district medical societies.

ROBERT N. NYE, *Secretary pro tempore*

## APPENDIX

ADMISSIONS RECORDED FROM MAY 22, 1940,  
TO MAY 22, 1941

YEAR OF ADMISSION	RESIDENCE	MEDICAL COUNCIL
1941	Ahrams, Herbert, Lowell	12
1940	Adams, Edward Everett, Roslindale	10
1941	*Adler, Alexandra, Boston	52
1941	Allan, Malcolm Stuart, Palmer	12
1940	Allen, Edward Carson, Brookline	12

## MEDICAL PROGRESS

### PHYSIOLOGY\*

HEBBEL E. HOFF, M.D.†

NEW HAVEN, CONNECTICUT

THE increasing threat of war has directed the attention of physicians to some of the immediate medical problems created by war. The background of many of these problems lies in the work done in peacetime, with entirely different objectives. With this in mind, I have devoted this year's report to a consideration of the physiologic background of certain questions of topical interest.

#### ANOXEMIA IN THE NERVOUS SYSTEM

The brain is unusually susceptible to deprivation of oxygen. In contrast to many other tissues such as muscle, the dominant respiratory process in the brain in vivo is the oxidation of glucose, so that even momentary lack of oxygen seriously interrupts its metabolic activity.<sup>1</sup> Complete interruption of cerebral circulation produces unconsciousness in six to eight seconds, and all electrical signs of activity in the brain are obliterated in twenty seconds.<sup>2</sup> An anemia of two to fifteen minutes gives rise to irreversible changes in the cortex and medulla, and temporary blindness may follow anoxemia for five minutes.<sup>3</sup> The centers in the brain stem regulating respiration and the cardiovascular system are much more resistant, and may show recovery after complete anemia for as long as thirty to fifty minutes. This difference in the vitality of respiratory and cardiovascular centers and the cortex probably accounts for the cases not infrequently seen in which patients recover from respiratory failure under anesthesia, or from carbon monoxide poisoning, but show signs of irreversible cortical damage.

The electrical activity of the brain may be used as an index of cortical anemia.<sup>4</sup> Usually, no changes are seen until the venous blood from the brain shows an oxygen content below 30 per cent saturation (normal, 60 per cent). Then the faster alpha waves begin to diminish in frequency and amplitude, after an occasional initial period of increased rate. There then appears an augmentation in frequency and amplitude of the slower delta waves, and if the anemia persists and deepens, these waves may entirely replace the alpha waves.<sup>5</sup>

Seizurelike discharges may occur.<sup>4, 5</sup> Finally, all waves disappear.

States in which there is a cerebral anemia result in a similar type of electroencephalogram, characterized by the predominance of delta waves. Among these are carbon monoxide poisoning, nitrous oxide anesthesia with insufficient oxygen,<sup>6</sup> a reduced blood carbon dioxide level, and increased intracranial pressure.<sup>4</sup> It appears that a low blood carbon dioxide level causes constriction of the cerebral arteries, which may be sufficient to produce anemia. Increased intracranial pressure, whether from tumor, trauma or hemorrhage, apparently produces no changes until the intracranial pressure approaches to within 40 mm. of mercury of the arterial blood pressure.<sup>7, 8</sup> Any increase from this point diminishes the cerebral circulation, and is followed by the characteristic signs of cerebral anoxemia.

Many authors have emphasized the close relation between the influence of anoxemia and hypoglycemia on the brain.<sup>1, 5</sup> The general symptoms as seen in the various so-called "shock" treatments of mental illnesses appear to be much the same, whether the shock is produced by low blood sugar or by anoxemia.<sup>4</sup> The electroencephalogram in hypoglycemia is also very similar to that in anoxemia.<sup>9-11</sup> Changes appear when the blood-sugar level (in the internal jugular veins) falls below 35 mg. per 100 cc., and consist in an early decrease in rate and amplitude of alpha waves, followed by an increase in amplitude and frequency of the delta waves.<sup>4</sup> When the dependence of the brain on glucose oxidation is recalled, it is understandable that deprivation of either glucose or oxygen should have similar effects.<sup>1</sup>

These studies have an obvious relation to the problems of aviation. As the altitude at which a plane flies increases, the partial pressure of oxygen decreases, and symptoms of anoxemia begin to appear. In general, most persons begin to show increased respiration at from 6000 to 10,000 feet. Symptoms of sleepiness, fatigue and headache usually appear at 10,000 to 12,000 feet. Impairment of cerebral functions may be evident at from 8000 to 15,000 feet, individual variations being considerable. Above 20,000 feet, there is a critical danger to life, and coma and convulsions may be

All articles in this series will be published in book form; the current volume is *Medical Progress: An annual, 1940* (Springfield, Illinois: Charles C. Thomas Company, 1941. \$4.00).

\*From the Laboratory of Physiology, Yale University School of Medicine.

†Associate professor of physiology, Yale University School of Medicine.

expected. Naturally, physical exercise or small amounts of carbon monoxide in the inspired air may greatly lower the altitude at which alarming effects of anoxemia may occur.<sup>12</sup>

Recent studies of the reaction of respiratory mechanism to anoxemia are of interest because of their applicability to the problems of high altitude flying and of general anesthesia. Schmidt and Comroe have for some time called attention to the major importance of the carotid body in the mediation of respiratory changes in response to low oxygen, whereas the respiratory center itself responds to increased carbon dioxide. In passing, it should be remarked that one of these authors<sup>13</sup> has recently made series of minute injections into the respiratory center of acid solutions or of solutions containing sodium bicarbonate and carbon dioxide. Although the former solutions had very little influence on respiration, the latter produced a prompt increase in respiration. These experiments, therefore, add to the evidence that carbon dioxide, and not pH, is the adequate stimulus to the respiratory center.

Schmidt and Comroe<sup>12</sup> have offered evidence indicating that during anoxemia, or during deep narcosis, the respiratory center may be seriously impaired, so that the main drive to the respiration is afforded by the carotid body. When, in such circumstances, the oxygen content of the blood is suddenly increased, the carotid body also ceases to function, and the center is unable to carry out its function alone. Respiration then ceases, and may fail long enough to cause death. The authors suggest that this may be the mechanism of respiratory failure in operations in which oxygen is administered after a period of anoxemia, and warn that delay in starting to use oxygen may create an anoxemia that will make possible similar accidents when oxygen is finally taken.

The autonomic nervous system is also involved in the reactions to anoxemia. The increased rate of the heart, the elevation of the blood pressure and the contraction of the spleen appear early and become increasingly noticeable as the anoxemia progresses. They are seen in experimental animals and in man during exposure to low atmospheric pressures,<sup>14</sup> and point to stimulation of the sympathetic nervous system. There may often occur an abrupt crisis at a degree of anoxemia near that which may produce unconsciousness; the heart suddenly slows, auriculoventricular block appears, and the subject becomes pale and sweaty, and faints. These symptoms point to an overaction of the parasympathetic nervous system and, thus, may in part be prevented by atropine.

Such observations do not permit the conclusion that the type of autonomic response depends on

the intensity of the anoxemia. On the contrary, there is recent evidence that during asphyxia both sympathetic and parasympathetic systems are stimulated simultaneously (Hodes,<sup>15</sup> Feldman, Cortell and Gellhorn<sup>16</sup>). Hodes compared the response of normal and sympathectomized animals to exercise and found that, although the normal cat showed a marked acceleration, the sympathectomized cat showed a decrease in rate. He suggests that muscular exercise produces a local vasodilatation, which cannot be compensated for in the sympathectomized cat. The blood pressure then falls, cerebral circulation becomes inadequate, and cerebral anoxemia results. The cerebral anoxemia then stimulates the sympathetic and parasympathetic centers, and the sympathectomy permits the parasympathetic responses to develop without opposition. Feldman, Cortell and Gellhorn arrive at the same conclusion after demonstrating that, in the normal rat, anoxemia (breathing 7 per cent oxygen) causes a rise in blood sugar, whereas it causes a hypoglycemia in the adrenalectomized animal.

#### ANOXEMIA IN THE HEART

The electrocardiogram serves as the most valuable indication of the presence and extent of anoxemia in the heart. Analysis of the voluminous literature of clinical and experimental studies permits the following general conclusions to be drawn. When the oxygen content of arterial blood is reduced from 30 to 50 per cent by any of a variety of procedures, such as breathing air containing a reduced (12 per cent) oxygen content, a progressive diminution of the height of the T wave is noted. This reduction in the amplitude of the T wave, which may eventually progress to inversion, is seen in all three standard leads, and has been observed in man as well as experimental animals.<sup>17-19</sup> It has been observed in aviators during ascents to 5000 feet or over without supplementary oxygen.<sup>20</sup> There is occasionally some displacement of the RST segment, usually downward. When the oxygen content of the arterial blood is reduced below 50 per cent saturation, changes resembling those in myocardial infarction appear. These include further displacement of the RST segment (often elevation), and the development of the so called "coronary T wave." Increase in the amplitude of the Q wave is not a prominent feature. If the deficiency of oxygen is neither too severe nor too prolonged, no anatomic changes are found in the heart, although the electrocardiographic changes may persist for some time.<sup>21</sup> If the anoxemia is severer, and persists but does not entail complete deprivation of oxygen, some necrosis will occur, which is distributed in small

foci that are largely subendocardial. These will be replaced in time by diffuse fibrous tissue. Carbon monoxide poisoning in man has been found to produce just such a picture.<sup>22</sup> Various German authors have for some time pointed out that this type of necrosis occurs in coronary disease in which the vessels are narrowed enough to cause serious restriction of the coronary blood supply but still permit sufficient circulation to prevent massive infarction.

Master and his collaborators<sup>23</sup> have recently shown that this type of myocardial damage is associated with electrocardiographic changes indicative of the lesser degree of anoxemia described above, that is, reduction in amplitude of the T wave and slight depression of the RST segment, and propose the term "coronary insufficiency" to designate the condition. Their use of the term "coronary occlusion" for the state associated with massive myocardial infarction is perhaps less justified, especially in view of the most recent work of Blumgart, Schlesinger and Zoll,<sup>24</sup> who show that coronary occlusion may often occur without infarction.

#### THE NATURE OF THE ELECTROCARDIOGRAM

An adequate explanation for the changes seen in the electrocardiogram during anoxemia, and after massive infarction of the myocardium, is not yet available, largely because there is as yet no adequate explanation for the normal electrocardiogram. There has been, however, some recent work on this subject. Some time ago, Eppinger and Rothberger<sup>25</sup> made superficial lesions in the heart by various methods (for example, the injection of corrosives) and found that the surface injuries produced marked effects, whereas deep injuries, not affecting the surface, evoked only minor changes, if any. They concluded that the electrocardiogram was largely determined by the electrical activity of the surface of the heart. Recently the subject has been reinvestigated by other methods,<sup>26, 27</sup> which confirm the thesis of Eppinger and Rothberger.

One of the procedures<sup>27</sup> employed in the above studies consisted in treating the heart with isotonic solutions of potassium chloride, which were found to cause a local and reversible depolarization, similar to that produced by an injury. Areas of the surface of the ventricles thus treated failed to develop their normal action potentials, and the influence of this failure on the electrocardiogram could be determined. When the left ventricle was so treated, elevation of the RST segment appeared in all three conventional leads. The elevation increased as more and more of the surface was involved, until finally an upright monophasiclike

complex remained. Since this remained after maximal injury to the left ventricle, it was concluded that this complex represented the contribution of the right ventricle to the electrocardiogram, that is, the "dextrocardiogram." Injury to the right ventricle, on the contrary, produced a depression of the RST segment, which increased with extension of the area of injury until an inverted monophasiclike complex remained after maximal injury to the right ventricle. It appeared that this complex represented the contribution of the left ventricle to the electrocardiogram, that is, the "levocardigram." Other evidence proved that the dextrocardiogram and levocardigram were in fact derived from the right and left ventricles, respectively. When these curves were plotted, and summed algebraically, complexes closely resembling the normal QRST complexes were obtained. It was concluded that the normal electrocardiogram results from the algebraic summation of the dextrocardiogram and levocardigram.

Elevation of the RST segment may therefore be taken to indicate damage to the left ventricle, whereas depression denotes damage to the right ventricle. When the lesion is restricted to a single ventricle, the RST segment is displaced in the same direction in all three conventional leads, although the greatest displacement occurs in Lead 2. When, however, the injury involves areas of both the right and the left ventricle, Leads 1 and 3 show the maximal changes, and the displacement in one lead is opposite to that in the other. With lesions of the anterior surface of the right and left ventricles, elevation of RST occurs in Lead 1, together with depression in Lead 3. Posterior damage involving both ventricles causes depression of RST in Lead 1 and elevation in Lead 3.<sup>28</sup>

According to the theory outlined above, the T wave represents the algebraic summation of the terminal portions of the dextrocardiogram and levocardigram. Normally, the right ventricle is excited slightly before the left, producing the normal upright R wave. If the durations of the dextrocardiogram and levocardigram are equal, the latter would be expected to terminate after the former, since it begins somewhat later. The T wave would therefore be downward. If for any reason the dextrocardiogram were prolonged beyond the termination of the levocardigram, the T wave would be upright. Alterations in the relative durations of the dextrocardiogram and levocardigram were actually produced by local heating and cooling of the surface of the ventricles, and concomitant changes in the T wave of the electrocardiogram appeared that were in every detail consistent with these theoretical postulations.<sup>29</sup>

Studying the effects of coronary occlusion by means of direct and semidirect leads, Jachim and his associates<sup>30</sup> concluded that three different factors play a part in the production of the characteristic electrocardiographic patterns: disturbances in conduction, partial or complete depolarization in the area of greatest injury, with consequent failure of action potentials from this area, and delayed repolarization in tissue that although damaged remains excitable and produces an action potential when stimulated. In view of the similarity between the monophasic action current and the dextrocardiogram and levocardigram, it is more than likely that the postulates of these authors, which now apply to the electrogram derived from direct leads, may be extended to the electrocardiogram. The effects of anoxemia on the electrocardiogram should then find explanation in the influence of anoxemia on the dextrocardiogram or levocardigram.

#### SITOCK

Freeman et al.<sup>31</sup> believe that at least one factor in the causation of shock is overactivity of the sympathetic nervous system. It may be induced reflexly by the fall in blood pressure in hemorrhage, by the afferent nervous stimulation in trauma or by the cortical stimulation of concussion, and it serves the normal function of maintaining blood pressure. If, however, the stimulus that has produced the overactivity continues, the latter may progress to a pathological degree. Peripheral arterial constriction will then diminish blood flow in the periphery to such a degree that capillary anoxemia occurs. Capillary anoxemia will be followed by dilatation of the capillaries, by fluid loss from the blood stream, by increased blood concentration, and by a progressively falling blood pressure—in other words, by shock. Freeman has shown that shock may develop in animals following slow constant infusion of adrenalin into the blood stream, which is confirmed by Swingle et al.<sup>32</sup> Other authors doubt whether the adrenalin-sympathetic theory can be applied to all types of shock,<sup>33</sup> and present experiments which appear to show that the administration of adrenalin may be a helpful therapeutic measure in shock consequent to intestinal manipulation.<sup>34</sup>

It is more than likely that a variety of factors are involved in the genesis of the syndrome generally recognized as shock. One important example comes from renewed interest in the influence on shock of extracts of the adrenal cortex and allied substances. Swingle and his co-workers<sup>32</sup> have demonstrated that additional cortical extract will protect against shock caused by trauma, by intra-

peritoneal injections of glucose or by injections of adrenalin in adrenalectomized animals maintained on adequate amounts of cortical extract. These authors then studied the effectiveness in these situations of desoxycorticosterone, a synthetic substance that appears to have the same effect on mineral metabolism as cortical extract. Desoxycorticosterone, used prophylactically, protected against shock induced by trauma, by injection of glucose into the peritoneal cavity and by injection of adrenalin. It had no effect on the shock following intestinal stripping.

The efficacy of adrenocortical extracts in the prophylaxis of shock of course raises the question of the relation of potassium to the various symptoms of shock. There is evidence that serum potassium may rise in shock.<sup>35</sup> Study of the influence of slowly rising concentrations of potassium in normal dogs makes it questionable whether increases in potassium, below levels required to kill the animal, cause any of the symptoms of shock.<sup>36</sup> Whether potassium is responsible for death in shock cannot be stated. Recent studies have established criteria by which the question may be judged.<sup>37</sup> Serum potassium should be in the neighborhood of 15 milliequiv. per liter in the presence of a normal serum calcium. Much higher levels of potassium may be reached if the calcium is elevated.<sup>38</sup> Accompanying the rise in serum potassium, a characteristic sequence of electrocardiographic changes should appear in the following order: increase in the amplitude of the T wave, depression of the ST segment, disappearance of the P wave, intraventricular block and arrest, or terminal ventricular fibrillation. At present the only situation (apart from poisoning from injection of potassium) in which accumulation of potassium has been shown to have caused death is in experimental anuria.<sup>39</sup> In dogs in which anuria was induced by ligation of the ureters or by removal of the kidneys, potassium steadily accumulated in the blood, and when it reached toxic levels the animals died.

There is now at hand a report of fatal shock in man accompanied by anuria, following a bomb blast.<sup>40</sup> Potassium in the serum rose to about 11 milliequiv. per liter at death. The patient died suddenly, with a rapid fall in blood pressure and an irregular pulse. The evidence in this case is entirely consistent with death from potassium poisoning, but without serial electrocardiograms it is difficult to be certain that this was actually so. It appears that the combination of shock and anuria will be a not infrequent occurrence after bomb-blast injuries.<sup>41</sup>

The use of desoxycorticosterone to prevent shock

may not be entirely without dangers. Extreme muscular weakness resembling familial periodic paralysis has followed the repeated injection in dogs of large doses of the substance.<sup>42</sup> There are also reports<sup>43, 44</sup> of the development of cardiac failure in man when large doses are given, and the condition also occurs in dogs. The difficulty may be diagnosed by the low serum potassium, and potassium added by mouth seems to be a specific remedy. It is possible that under some conditions prolonged periods of low potassium may result in pathologic changes in the heart.<sup>45</sup>

### HISTAMINE

The subject of shock naturally recalls the question of the role of histamine. Two general reviews of the subject are most valuable, because in both an attempt is made to delimit the action of histamine, and to indicate the circumstances in which histamine is not the causative agent, as well as those in which it is implicated.<sup>46, 47</sup> Evidence for histamine release is perhaps best established in the "triple response" of the skin to injury (Lewis<sup>48</sup>). The resemblance of the triple response to the response of local anaphylaxis in the skin led Lewis to conclude that the antibody-antigen reaction in sensitized skin cells represented a special form of cell injury, which like other stimuli injurious to cells caused the release of a preformed histaminelike substance. This naturally led to the concept that many responses in anaphylaxis of other types are due to the liberation of histamine.

The release of histamine seems to be particularly well established in the physical and nervous allergies. The allergic reaction to cold or heat, which may be accompanied by extreme vasodilatation and a fall in blood pressure, also causes an increased secretion of highly acid gastric juice, which appears to be good evidence that histamine is involved. The urticarial reactions to nervous stimuli, exercise and temperature changes reported by Grant, Pearson and Comeau<sup>49</sup> are similar to reactions caused by histamine, and are presumably due to the release of histamine by cholinergic nerve fibers in the skin of susceptible persons. In anaphylactic shock in dogs and rabbits, release of histamine can account for the major symptoms. Evidence is available to implicate histamine as the active factor in other types of human allergy, but cannot be said to be conclusive. The demonstration that histamine can be liberated in the skin of susceptible persons by cholinergic nervous stimulation strengthens the possibility that asthma of nervous origin may arise from the release of histamine in the lungs by vagal stimulation.

Histamine may also play a part in the genesis

of the symptom complex arising from bacterial or other intoxication. The acute collapse following administration of the toxin of *Staphylococcus aureus* has been shown to result from the liberation of histamine.<sup>50</sup> Certain snake venoms also release histamine. In all these circumstances, other effects of the toxic agent may also appear, and may produce symptoms. Thus mercuric chloride liberates histamine,<sup>50</sup> but it also coagulates protein, both factors being important. On the whole, Feldberg<sup>46</sup> concludes that the acute effects of the intoxication are likely to be histamine effects, whereas the chronic effects are likely to be results of other actions of the intoxicating agent. It is of interest that a disease in horses can be shown to be due to the action of certain bacteria in the gastrointestinal tract, which decarboxylates the amino acid histidine to form histamine. Feldberg also points out that a diversity of quite unrelated factors may operate to liberate histamine, such as simple coagulation of cell protein, dissolution of lipoprotein combinations within the cell and mechanical injury. The substance therefore appears to be in some sort of union with the cellular protein.

Some reports have appeared of the successful use of histaminase to reduce the response of reactive cells to histamine. Other attempts have not been uniformly successful.<sup>40</sup>

### HIGH-PROTEIN DIET AS A PROTECTION AGAINST LIVER INJURY

The well-established practice of giving diets high in carbohydrate in conditions in which liver damage is a factor may require modification in view of recent experimental data, which indicate the even greater protection afforded by a diet high in protein.<sup>51</sup> Using chloroform as the toxic agent, Ravdin and his associates<sup>52</sup> found that starved animals were more susceptible, whereas animals fed high-protein diets were much more resistant than normal animals. Miller and Whipple<sup>53</sup> have confirmed these experiments in the dog. They find that a normal well-fed dog will tolerate an hour of chloroform anesthesia without showing liver necrosis. Normal dogs fasted for three days respond to the same treatment by the development of marked hyaline central necrosis of the liver, marked lowering of prothrombin and fibrinogen in the blood, increase in the bile pigment in the liver, increase in urinary nitrogen and clinical signs of intoxication. Some animals die in two to four days. Dogs with low serum protein (low-protein diets or plasmapheresis) can hardly tolerate fifteen to twenty minutes of anesthesia. A single large protein feeding will markedly increase the resist-

ance of these dogs to chloroform. The protective effect of certain irritant substances (sodium ricinoleate and colloidal carbon) may be due to the inflammatory reactions they evoke, and to the consequent increased protein catabolism.<sup>51</sup> There is some evidence that the sulfur-containing amino-acids have a role in the protective influence of protein.

A variety of other toxic agents affecting the liver are also shown to be influenced by a high protein diet. The most important is perhaps arsphenamine, which at times may cause liver damage when used therapeutically. Using admittedly high doses (0.03 gm. per kilogram) Messinger and Hawkins<sup>52</sup> found that both high-protein and high carbohydrate diets were protective, whereas fat diets were harmful. The toxic effects of selenium on the liver are also determined by the diet. A high-protein diet greatly reduces the liver damage produced by feeding selenium-containing wheat.<sup>53</sup> Lewis, Schultz, and Gortner,<sup>54</sup> who noted the increased resistance to selenium afforded by a diet containing 30 per cent casein rather than 6 per cent, found that methionine was protective, whereas cystine in equivalent dosage was not, although both are sulfur-containing aminoacids.

These studies emphasize two very practical points. First, they call attention, if this is still necessary, to the extreme hazards accompanying the use of chloroform as an anesthetic, especially if anoxemia is also a factor.<sup>55</sup> Secondly, they suggest that a high protein, high carbohydrate diet is required in any condition in which liver damage must be combated or prevented.

Associated with this problem are reports showing that a gum acacia, given for its osmotic pressure effect, accumulates in the liver and depresses certain liver functions.<sup>56-58</sup> Large quantities of the material may accumulate in the liver, and there act to diminish the production of plasma proteins, affecting most seriously the fibrinogen.<sup>51, 52</sup> Other liver-damaging substances enhance the depression of plasma proteins by acacia.<sup>59</sup> The depression of plasma proteins may last for several months after cessation of acacia injections, and the enlarged acacia-filled liver may persist for a long time. There is one report of its presence in the liver of a child to whom it was given six years previously.<sup>61</sup> Acacia does not appear to affect the production of bile salts or bile pigments, nor is it responsible for the alteration in blood and bile cholesterol.<sup>62</sup>

### CASE 27271

#### PRESENTATION OF CASE

*First Admission* A forty-four-year-old Italian carpenter entered with the complaint of intermittent pain in the epigastrium of about three years' duration. Starting as a sensation of "knowing" in the epigastrium frequently associated with "burning" between the shoulder blades, it became progressively severer, developing into a sharp pain, which characteristically occurred thrice daily at 11 a.m., 5 p.m. and 11 p.m. and was readily relieved for a few hours by food or powders. Occasionally, the patient was awakened from sleep by an attack of pain, and on such occasions he usually felt nauseated. He rarely vomited, and the vomitus was never blood stained or black. He had never noted any black stools. During the first two years, his attacks had been interspersed between comparatively long periods of complete freedom from symptoms. In the last five months there had been no significant remission. He had lost about 25 pounds in the year before entry.

Nine months before admission the patient had visited the Out Patient Department, where a gastrointestinal series was reported as follows: "Examination of the esophagus shows no evidence of varices or herniation. The stomach is high in position and fills well. There is definite tenderness over the lesser curvature about 6 cm. from the hiatus, where there is an ulceration 1.5 cm. in width which extends 1 cm. outward from the body of the stomach. The antrum shows considerable spasm. The duodenal cap fills well and shows normal relief. The findings are those of a large gastric ulcer on the lesser curvature." A six meal bland diet was prescribed, with transient relief, but was not adhered to. An x-ray examination after seven months still showed the ulcer crater, although it seemed definitely shallower than on the first examination. Because of his unsatisfactory progress, hospitalization was advised.

The past history recorded an episode of "anemia" during service in the Italian army twenty years before, which was treated with a series of thirty-six daily gluteal injections. The patient's father was living and well at seventy-two, his mother

had died at fifty of unknown cause. One brother had attacks of "stomach trouble" associated with the vomiting of bright-red blood. His wife had had four children, all of whom were living and well.

Physical examination showed a sparse, muscular man lying comfortably flat in bed in no distress. The skin and mucous membranes showed no icterus or pallor. The nasal septum was deviated to the left. The teeth were carious, with some bleeding of the gums. The heart and lungs were normal, the blood pressure 100 systolic, 70 diastolic. Abdominal examination disclosed no tenderness, and no masses or organs could be felt. Rectal examination showed small hemorrhoidal varices. Reflexes were normal.

The temperature was normal, the pulse from 70 to 80, and the respirations from 15 to 20.

Laboratory examinations included a negative blood Hinton reaction. The red cell blood counts ranged from 4,700,000 to 4,900,000, the hemoglobins from 84 to 90 per cent (Tallqvist), and the white-cell counts from 7000 to 11,000. The differential count was 54 per cent polymorphonuclears, 34 per cent lymphocytes, 21 per cent monocytes and 2 per cent eosinophils. There were no abnormal cells, and the red cells showed no abnormalities. The urine varied from 1016 to 1030 in specific gravity and never showed albumin, sugar, diacetic acid or bile. The sediment was normal. Fifteen stools were brown in color and negative to the guaiac test. Two serum protein determinations showed 6.6 and 7.0 gm per 100 cc. The nonprotein nitrogen was 22 mg per 100 cc., and the blood chloride 101.6 milliequiv. per liter. A gastric analysis showed no free hydrochloric acid in the fasting contents, but 50 units after histamine.

The patient was placed on a regime of strict bed rest, a first stage ulcer diet, Amphogel and tincture of belladonna supplemented by subcutaneous atropine. His improvement was steady. Three x-ray examinations at intervals of approximately two weeks reported respectively: "The ulcer crater is definitely smaller and now measures 8 mm. in diameter", "The crater is much smaller and now measures approximately 2 to 3 mm. in diameter", "An ulcer crater is no longer visible." All reports, however, including the last, described shortening of the lesser curvature and spasm in the prepyloric area. Deformity of the duodenal cap was mentioned twice, but no spasm or evidence of active ulceration was noted. Two gastroscopic examinations were performed during the same period. The first described a typical benign ulcer 0.5 cm. in diameter, with slight granularity of the

surrounding mucosa. On the second examination no ulcer could be seen. The patient was discharged after nine weeks, apparently relieved.

*Second Admission* (nine months later). During the succeeding period, the patient was seen at irregular intervals in the gastrointestinal clinic of the Out Patient Department. Despite adherence to a six-meal diet, he had some discomfort almost every day, usually a sensation of burning between the shoulder blades rather than epigastric pain. X-ray examinations one and two months after discharge were inconclusive, mentioning spasm in the prepyloric area and questionable irregularity of the lesser curvature proximal to the area of spasm. The following month a gastroscopic examination demonstrated recurrence of the ulcer, with a crater 1 cm. in diameter and approximately 3 mm. in depth. The patient was advised to re-enter the hospital, but refused and disappeared for an interval of six months. On return he reported an episode two months before of increasing pain for several days followed by vomiting a large amount of bright-red blood and fainting. He was taken to another hospital, where he remained one week. In the two weeks before entry his pain had become severer and was no longer relieved by food or soda. An x-ray examination in the Out Patient Department was reported as follows: "Examination shows a normal esophagus and a high stomach, which lies in the transverse position and is beyond the reach of palpation." An ulcer could again be demonstrated on the lesser curvature almost as large as that noted at the first examination. The lesser curvature in the neighborhood of this ulcer appeared somewhat rigid and edematous. There was again spasticity of the prepyloric area, but this area opened up during the examination, filled and emptied well. The duodenal cap and remainder of the duodenum showed nothing abnormal. The mucosal folds in the stomach appeared somewhat hypertrophic. The diagnosis was "ulcer of the lesser curvature, which appears benign." Hospitalization was again advised, and the patient re-entered.

Physical examination was essentially unchanged, except that the mucous membranes showed pallor and the blood pressure was 140 systolic, 90 diastolic. His weight was 131 pounds, as compared with 126 on the first admission. The heart, lungs and abdomen were entirely normal. Examination of the blood showed a red-cell count of 4,900,000 with a hemoglobin of 10.5 gm., and a white-cell count of 8800. The differential count was 57 per cent polymorphonuclears, 24 per cent lymphocytes, 8 per cent monocytes, 10 per cent eosinophils and 1 per cent basophils. There were moderate achromia and variation in the size and

shape of the red cells. One of two urine examinations showed a + test for albumin. Two stool examinations were guaiac negative. A gastric analysis showed 18 units of free hydrochloric acid in the fasting contents and 41 units after histamine. The material was guaiac negative.

On the sixth hospital day a laparotomy was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. HELEN PITTMAN: This seems to me like a very run-of-the-mill case.

I do not know anything about Italian medicine, but according to the little I know about French medicine everything is treated by injection, and I should assume that this patient had just what the record states, "an episode of anemia," and I am going to disregard it as having anything to do with the rest of the case.

The only interesting points in the laboratory findings are the 21 per cent monocytes, not borne out by a later count, and the absence of free acid in the fasting contents but the presence of acid after histamine. The two differential counts do not compare. One shows 21 per cent monocytes and 2 per cent eosinophils, and the next had 8 per cent monocytes and 10 per cent eosinophils. I shall assume that it is not very important.

Perhaps this would be a good time to see the x-ray films.

DR. TRACY B. MALLORY: I shall show lantern slides of the films. The lesion is so obvious that I can point it out without benefit of a roentgenologist. This was taken in March, 1939, showing a good-sized crater, situated just about the middle of the lesser curvature. The second slide shows the stomach a year and a month later, and the crater is absent. In the third picture, one year subsequently, it is back again and is of the same size as in the first examination.

DR. PITTMAN: I think that this is a perfectly classic story of recurrent gastric ulcer, which did very well in the hospital under supervision. When the patient returned home and was not under supervision it recurred, although he said he had adhered to his diet. He was operated on because of the danger of its being carcinomatous. I think he should have been operated on, and I should think no one would be able to tell what they were going to find.

The physical findings on the whole were quite normal. The patient developed no anemia; he had one period of frank bleeding, but no occult blood. His weight kept up; he had always had acid after histamine, and free acid was present at the second entry. I do not believe it is possible to

say whether he had a carcinoma or whether he had an ulcer. On the basis of the facts that he had not developed anemia, that he had not lost weight and that the general condition apparently was very good, I am going to guess that when they operated he still had a benign gastric ulcer.

DR. AUBREY O. HAMPTON: We could not tell any more than anyone else about this case. The diagnosis depends on the histology. The fact that the ulcer reduced in size—perhaps it did not quite disappear, but we thought it did—does not rule out carcinoma. Although some years ago I should have been fairly certain it was a benign ulcer, at present I am skeptical.

DR. EDWARD B. BENEDICT: I did three gastroscopies on this patient. At the first examination the lesion looked essentially benign. I thought he should be carefully followed. Two weeks later I did another gastroscopy and saw no ulcer, but pointed out the fact that it might be hiding behind the angulus. There is a blind spot where it is possible to miss an ulcer, and I still advised following him carefully by x-ray study and by gastroscopy. Two months later I saw him again and gastroscopied him, and the ulcer was there again. The recurrent ulcer still looked grossly benign, but I questioned the possibility of malignancy and advised him to enter the house. I think that from then on the history is misleading. I am quite sure he was completely lost track of for seven or eight months and not seen in the clinic. He refused to re-enter the hospital. When I next saw him this winter, x-ray study showed a definite recurrence, and the patient was advised to come in for resection.

DR. LELAND S. MCKITTRICK: Were you or any one else worried about the shortening of the lesser curvature described?

DR. HAMPTON: No. At one time that was thought to be commoner in benign than in malignant lesions, but I do not believe it is worth anything in the differential diagnosis. It means only spasm of the longitudinal muscles. It could occur in either type of lesion.

DR. HORATIO ROGERS: I should think the assumption would have been that this was malignant. With his age, with the change of symptoms and with the recurrence of the ulcer, I should have considered it malignant rather than benign. I am surprised that they assumed it the other way. What was the objection to operation at the first admission?

DR. BENEDICT: We advised hospitalization on the basis of potential malignancy when first seen in the Gastrointestinal Clinic, but the patient refused to come in.

DR. ROGERS: What is the prognosis of a man

of this age with an ulcer more than a centimeter in diameter in the stomach?

DR. HAMPTON: I do not know.

DR. MCKITTRICK: Do you not believe, if you want to be critical, you should go back nine months and ask why he had not been hospitalized when the diagnosis of gastric ulcer was first made?

DR. BENEDICT: Yes; nine months previously he was seen in our gastrointestinal clinic. Cancer should have been seriously considered, although the ulcer was not very large.

DR. MCKITTRICK: I do not care how large it is, Dr. Benedict. I think there is only one way to treat ulcers of the stomach and that is to treat them all in the hospital as soon as the diagnosis is made. The patient should become symptom free and the ulcer heal and remain healed, or else operation is indicated.

DR. BENEDICT: I agree, but the patient would not come in.

#### CLINICAL DIAGNOSIS

Peptic ulcer, benign

#### DR. PITTMAN'S DIAGNOSIS

Recurrent gastric ulcer.

#### ANATOMICAL DIAGNOSIS

Carcinoma of the stomach, with secondary peptic ulceration.

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: This patient was operated on, and a lesion was found, which could not be differentiated from a benign ulcer. It was resected, and in gross it was impossible for the pathologist to say that it was anything other than a benign ulcer. When microscopic sections were made, it was apparent that there was something more. There was a deep area of peptic ulceration, lined by a typical fibrinoid layer, that had completely penetrated the muscularis and produced extensive scarring of the serosa. One small lymph node was drawn into the scar tissue, and sections through it showed a small focus, only 2 mm. in diameter, of colloid carcinoma, obviously a metastasis. Most of the ulcer appeared perfectly benign; no tumor could be found underneath the penetrating portion, but when its margins were examined it was quite clear that the mucosa, although of normal thickness, consisted entirely of malignant cells, a few of which were of the signet-ring type found in the lymph node. In most sections the tumor was entirely limited to the mucosa, but in one a submucosal lymphatic was found plugged with a thrombus of tumor cells.

Unquestionably in the interval during which the patient was observed this tumor changed from a carcinoma in situ to a frank invasive tumor, and metastasis developed. If the patient had been operated on while the cancer was still in situ, his chance of cure would have been better than 80 per cent, perhaps 100 per cent. It is doubtful if a tumor can metastasize until it begins to invade. With frank invasion and metastasis to a regional node, the chance of survival drops to about 30 per cent, even though it is still an early cancer.

### CASE 27272

#### PRESENTATION OF CASE

A twenty-two-year-old college girl entered the hospital complaining of epigastric pain and tenderness.

Five months before admission, at a time when the patient had been working very hard during and after school, she suddenly felt nauseated and vomited without apparent cause. The next day she began to have attacks of epigastric pain of unstated duration, which were severe enough to double her up. After several weeks of suffering, the patient consulted her physician, who made a diagnosis of peptic ulcer and prescribed hourly feedings and soda. This treatment gave only partial relief, and she found that warm milk was the most effective antidote. At no time had there been a change in bowel habits, melena, jaundice, vomiting or fever.

Two months before admission the patient married, and the attacks of epigastric pain grew worse, occurring in greatest severity about 1 a.m. At this time also the patient stated that she had had an attack of bronchitis, with fever, but no cough or hemoptysis. Six weeks before entry, she developed a sore mouth, and little blisters appeared on her gums and buccal mucous membranes. This condition grew worse until the patient was unable to eat and subsisted wholly on liquids for a few days. Her physician found that her gums were swollen and bled easily and prescribed a perborate mouth wash, orange juice, thiamine chloride and nicotinic acid, with the result that the condition cleared in five days. Three weeks before admission the epigastric pain became still severer and it was found that her temperature was 101°F.; the red-cell count was 3,200,000, the hemoglobin 50 per cent, and the white-cell count 16,000. Iron and liver extract were given, and a few days later the patient developed diarrhea, with six bowel movements daily, but no blood was noticed. Profuse night sweats appeared, and it was found that her temperature ranged from

99 to 102°F. She had missed her last two menstrual periods and had lost 12 pounds since the beginning of her illness.

The patient had had the usual childhood diseases, scarlet fever, and malaria at the age of eight years while in the tropics. The family history was irrelevant.

On examination the patient was well developed, but poorly nourished, pale and very ill. Examination of the heart, lungs and abdomen was negative except for slight epigastric tenderness; the blood pressure was 120 systolic, 48 diastolic. Pelvic examination was negative.

The temperature was 102°F., the pulse 90, and the respirations 30.

The urine was normal. The blood showed a red-cell count of 2,010,000 with a hemoglobin of 3 gm. (photoelectric-cell technic), and a white-cell count of 24,100 with 77 per cent polymorphonuclears. The sedimentation rate was 0.6 mm. per minute. The nonprotein nitrogen of the blood serum was 20 mg., and the protein 5.5 gm. per 100 cc. The blood Hinton reaction was negative. The stools were formed and black, and gave a ++++ guaiac test.

An x-ray film of the chest showed a primary complex in the right lower-lung field, with increased hilar calcification, but the lung fields were clear and the heart was not remarkable.

A gastrointestinal series showed a large mass occupying the greater portion of the body of the stomach, starting at the cardia and extending to an area approximately 4 cm. proximal to the pylorus. A large ulceration was present within the mass. The hourly follow-up films showed normal speed of transport through the small intestine. The loops of ileum were slightly dilated, and the barium within them had a somewhat pasty appearance.

One week after admission, gastroscopy was performed, and just inside the cardiac orifice about 2 or 3 cm. below the cardia was a smooth, rounded neoplasm projecting from the lesser curvature and involving the anterior and posterior walls, elevated above the surrounding mucosa 3 cm. or more and extending down at least to the angulus. In the central portion of the tumor there was an ulcerated, whitish sloughing area. In various portions there was definite hemorrhage, and old blood was present on the greater curvature. The angulus could not be identified, and the antrum and pylorus were not visible.

Three days later, peritoneoscopy was performed. A few ounces of clear fluid were aspirated from the peritoneal cavity, the liver appeared normal, the lesser curvature of the stomach lay under the

liver but was not adherent to it, and no tumor could be seen in the stomach. There was no evidence of metastatic disease throughout the peritoneum. A mass the size of an orange in the right side of the pelvis had the appearance of a benign ovarian cyst. No tumor cells were identified in the peritoneal fluid on pathological examination. Within the next two weeks the patient was given six 500-cc blood transfusions. Her temperature varied between 100 and 105°F. for a short while, but gradually fell to 99°F.; the white-cell count fell to 10,000, and the red-cell count rose to 3,900,000.

On the fourteenth hospital day an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR THOMAS J. ANGLE: May we see the x-ray films?

DR. AUBREY O. HAMPTON: Here is the large ulcer described in the stomach, a huge ulcerating lesion involving the whole of the lesser curvature except a small portion of the antrum. This is, I assume, the mass described in the right side of the pelvis. You see it outlined here by pressure on the small bowel. The chest was normal as described.

DR. ANGLE: What is the relation of the mass to the markings here?

DR. HAMPTON: The mucosal folds of the stomach are very thick all around it. The spleen and the liver are not enlarged.

DR. ANGLE: We are presented in this case with a large mass of clear cut and definite objective data that leave very little doubt concerning the basic nature of the underlying lesions. The problem is chiefly one of filling in the details and deciding on the precise nature of the neoplasm, rather than on the fundamental nature of the disease. That seems to have been settled for us by the gastroscopist, who reported a definite neoplasm in the stomach, described as being a large, round, smooth tumor mass with a grayish sloughing ulcerated center, so that I think we may start with the assumption that we are dealing with a neoplasm. For the sake of completing the differential diagnosis, one might mention briefly in passing the possibility of granulomatous disease. The case history and the x-ray findings and the finding of the gastroscopist, however, do not seem to be consistent with a diagnosis of tuberculosis or syphilis of the stomach, and in both these diseases, which are relatively rare, the typical picture is one of rather shallow serpiginous ulceration, and does not seem to fit this picture at all. Hence I think we can dismiss granulomatous disease.

If it is neoplasm, what kind is it—malignant or benign? If malignant, is it an epithelial tumor or a tumor of mesodermal origin? On a purely statistical basis, carcinoma of the stomach is, of course, by a wide margin the commonest neoplasm of the stomach, and the story presented in this case is entirely consistent with a diagnosis of carcinoma of the stomach. But there are certain features of the story that are atypical. If it is carcinoma, it would have to be of the polypoid type to be reconciled with the finding on gastroscopy. Against the diagnosis of carcinoma is the age of the patient. Carcinoma is very uncommon at the age of twenty-two, but it cannot be ruled out entirely on that basis. Also against the diagnosis of carcinoma are the relative absence of impairment of gastric motility and emptying and the abrupt onset of symptoms. The other tumors of the stomach that must be considered are the benign and malignant tumors of mesodermal origin. These are leiomyoma and its malignant variant, leiomyosarcoma, neurogenic sarcoma and lymphosarcoma. I wonder if I can find out more about the details of gastroscopic examination before going on with the differential diagnosis. Hemorrhagic areas are mentioned. Were they in the ulcerated portion or in the surrounding, smooth portion of the tumor?

DR. EDWARD B. BENEDICT: They were in the ulcerated portion.

DR. ANGLE: I think the least likely of the mesodermal tumors is lymphosarcoma. It is a relatively rare disease. It occurs in a form that originates in the stomach, and in a form with gastric involvement arising on the basis of a generalized lymphosarcomatosis. The picture presented on gastroscopy in this case, however, does not seem to be consistent with lymphosarcoma. We have here a large round, smooth, hard mass with an ulcerated center. Lymphosarcoma usually presents smaller masses than the one described here, although occasionally a large lobulated irregular polypoid tumor does occur. Some of the features of gastric lymphosarcoma are a soft consistence, with marked general vascularity and with scattered hemorrhagic areas in various parts of the tumor. I do not gather from the description of the findings on gastroscopy that they were consistent with this diagnosis.

Of the other mesodermal tumors that occur in the stomach, one stands out as the most likely diagnosis in this case, the malignant variant of leiomyoma, leiomyosarcoma. The history is entirely consistent with this diagnosis. There are certain features of the history that are difficult to reconcile, but in general it fits perfectly adequately.

Leiomyoma is the commonest benign tumor occurring in the stomach, and its malignant variant, although much less common than carcinoma, is not rare. It characteristically manifests itself by causing gastric distress or pain, and is associated frequently with epigastric tenderness of varying degree. A very common symptom is hemorrhage, causing either hematemesis or melena, or both. That is one of the features in this case which is difficult to reconcile with the picture presented by the patient on admission. We are told that the patient had a ++++ guaiac test on the stools at admission, and that the stools were dark, but beyond that there is no previous mention of either hematemesis or melena. Otherwise she presented a story that is entirely consistent with the clinical features presented usually by people with this disease: epigastric distress, starting abruptly in a patient previously in apparently good health, followed by increasing epigastric pain and clinical evidence in the patient's general decline, suggesting chronic blood loss in spite of the absence of clear-cut hematemesis or melena. The gastroscopic findings are entirely typical, presenting the usual picture, seen in leiomyoma or leiomyosarcoma of the stomach, of a round smooth mass occupying a large portion of the stomach wall, either anterior or posterior, with a central ulcerative area, frequently associated with bleeding points or hemorrhage from that area. Also characteristic of this disease is the relative absence of impairment of gastric function. There is very little, if any, impairment of gastric emptying, which we should hardly expect if the patient had a cancer of this size.

The next most likely possibility of the connective-tissue tumors that must be considered is neurogenic sarcoma. Neurogenic sarcoma can simulate leiomyoma and leiomyosarcoma in every detail, so that it is impossible to make a differential diagnosis between them on clinical grounds. The diagnosis is usually made by the pathologist.

There are certain features of this case that seem difficult to relate to the diagnosis that I have suggested, for example, the high fever and the very marked degree of anemia without a definite clinical history of blood loss by hematemesis or melena, but I believe that the answer to this apparent discrepancy is that this patient did have severe chronic blood loss in spite of the absence of such a history. I believe that the high fever and the anemia are the result of severe recurrent hemorrhage into the gastrointestinal tract. In support of that opinion is the finding that the patient responded very quickly and very readily to repeated transfusion,

with a rapid rise in red-cell count and a rapid fall in fever. There are minor symptoms, which I shall mention in passing, that I do not believe have any relation to the fundamental underlying disease. The stomatitis mentioned may have developed on the basis of vitamin deficiency, or may have been due to dehydration or faulty oral hygiene. The fact that it responded quickly to vitamin therapy suggests that it may have been due to vitamin deficiency. The amenorrhea may have been the result of chronic blood loss or possibly of pregnancy. The findings on peritoneoscopy I do not believe help us much, except to exclude a generalized malignant lesion. I am willing to accept the gastroscopist's opinion that the pelvic mass was an ovarian cyst. I believe this patient most probably had a leiomyosarcoma of the stomach, with hemorrhage into the gastrointestinal tract, with neurogenic sarcoma as the second choice, and benign cyst of the ovary.

DR. TRACY B. MALLORY: Dr. Hampton, do you want to express an opinion on the basis of the x-ray findings?

DR. HAMPTON: I think Dr. Anglem has the wrong impression from Dr. Benedict's story. I do not consider it fair to say that the tumor mass was round.

DR. BENEDICT: Do not forget that I won a dollar from the X-ray Department on this case.

DR. HAMPTON: I do not care if you did. I should say that the mass was relatively flat, with a rolled margin. The whole mass was not round, and the area of ulceration is very extensive and not very deep. That is more like lymphoma than leiomyosarcoma.

DR. BENEDICT: The edges of it certainly were rounded.

DR. HAMPTON: Yes; the edges were, but the mass was not.

DR. MALLORY: Have you anything further, Dr. Benedict?

DR. BENEDICT: No; I think Dr. Anglem is to be congratulated on his discussion. He has considered everything. I was unable to reach a positive diagnosis. I mentioned the most likely things, — carcinoma, leiomyosarcoma and lymphoma, — but was not willing to say which it was. We considered an open-tube gastroscopy with biopsy to establish a positive diagnosis, but decided that the patient should be explored anyway, so that we did not do it.

#### CLINICAL DIAGNOSES

Carcinoma of stomach?

## DR. ANGLE'S DIAGNOSES

Leiomyosarcoma of stomach?  
Neurogenic sarcoma?  
Ovarian cyst, benign.

## ANATOMICAL DIAGNOSIS

Fibrosarcoma of stomach

## PATHOLOGICAL DISCUSSION

DR. MALLORY: This patient was operated on, and a subtotal gastrectomy was done. A large tumor involved the lesser curvature almost from the cardia to the pylorus, and was extensively ulcerated. It had involved the entire thickness of the gastric wall and had reached the serosa. In gross it was no more possible to make an exact diagnosis than it was on clinical examination, but microscopic examination showed a rapidly growing spindle-cell sarcoma that looked more like fibrosarcoma than leiomyosarcoma. A few mitotic

figures and a great many tumor giant cells were present. However, no visible metastases were found. A great many enlarged nodes were present in the attached omentum, but they showed only inflammatory hyperplasia and one would not expect this tumor to go to the nodes in any case. I should think the picture on the whole bore out Dr. Hampton's contention as to the appearance of the tumor. The margin was round, but the tumor on the whole was rather flat, with a very extensive irregular area of shallow ulceration.

DR. HAMPTON: Is that more typical in gross of lymphoma than leiomyosarcoma?

DR. MALLORY: Yes. A diffuse spindle cell sarcoma of the stomach, with widespread invasion of the stomach wall, is quite uncommon. I remember one other very much like this, but ordinarily a spindle-cell tumor is quite well localized and has a tendency to be spherical.

DR. HAMPTON: The ulcer is usually much smaller and much deeper. I think that is the reason we lost a dollar. Next time we shall win it.

## NURSING LEGISLATION

IN 1941, a bill to put control of nurses' registration and of nurses' training schools in a board of five nurses, with no representatives of the hospitals, physicians or public, was introduced by the Massachusetts Nurses Association. Hearings were held before the Committee on State Administration, and this committee has now reported out its own bill (House 2530), which increases the Board of Registration to four nurses and three physicians, including the secretary of the Board of Registration in Medicine *ex officio*. It provides for a paid nurse assistant to the secretary. This board is given control of registration.

The committee's bill also creates an approving authority to control all matters pertaining to training schools. This authority was composed as

follows: a nurse who is a faculty member of an approved school for nurses and a member of the Board of Registration; a nurse who is a faculty member of an approved school for attendants and a member of the Board of Registration; the secretary of the Board of Registration in Medicine; the commissioner of education; the commissioner of public health; a physician who is a superintendent or assistant superintendent of a hospital having an approved school for nurses or attendants; and a physician who is a member, with professorial rank, of the faculty of an approved medical school. The Massachusetts Hospital Association asked that the trustee of a charitable hospital be added, to represent the large interest of these institutions, and the Massachusetts Medical Society requested the addition of a practicing physician. With these additions, the bill has the approval of the Massachusetts Hospital Association and the Massachusetts Medical Society.

The bill also provides for the registration of attendants and approval of their schools.

The control of nursing schools, which are generally operated by hospitals, is thus placed in a committee composed of members representing the medical profession, the hospitals, the general public and nurses, and the bill also promotes the training of nursing attendants with recognized standing, to alleviate the shortage that is already occurring in the present emergency. This is as it should be. It is most important that the committee's recommendation be enacted into law.

## SIR D'ARCY POWER

THE death of Sir D'Arcy Power in England on May 18, 1941, at the age of eighty-five, brings to an end a useful career in both surgery and medical history. For nearly fifty years, D'Arcy Power was connected with St. Bartholomew's Hospital in London; he entered, as a student, in 1878 and left, as a consulting surgeon and one of the governors, in 1920. Few men have served a hospital for so long a period, and rarely has any-

\*Books, pamphlets and letters by Sir D'Arcy Power are now on exhibit in the rotunda of the Boston Medical Library.

one been more faithful to his parent institution. A few years after his retirement, he wrote *A Short History of St. Bartholomew's Hospital, 1123-1923* (1923), a fine example of what a hospital history should be. The chapters are brief and lively, and the illustrations, one in color showing the tomb of Rahere, founder of the hospital, form a unique feature of this admirable book.

The history of his own hospital, however, was not, by any means, the chief writing of D'Arcy Power. His bibliography goes back to 1881, when he published a little book, *Manual for the Physiological Laboratory*, with Vincent Harris, the demonstrator of physiology. At that time he was assistant demonstrator of the St. Bartholomew's Hospital Medical School and had joined the hospital staff in a subordinate position only a few years before.

As time went on, he continued to publish numerous works. One of his early books was *Surgical Diseases of Children* (1895), and in 1908 he edited *A System of Syphilis*, in six volumes, containing, among other chapters, an outstanding "Introduction" by Jonathan Hutchinson and a "History" by Iwan Bloch. These two sections gave the books a distinctive character, and along with the other contributions, all of them authoritative, made this system one of the great medical publications of all time. The work, moreover, may be read today with profit, and the "Introduction" and "History" are permanent contributions to literature.

D'Arcy Power also revised *Plarr's Lives of the Fellows of the Royal College of Surgeons of England* (1930), which consisted of two volumes. This work entailed a tremendous amount of careful research and is a monumental achievement. In research fields, moreover, Power edited a number of texts, such as John Arderne's two books, *Treatises of Fistula in Ano* (1910) and *De Arte Physicali et de Chirurgia* (1922).

In 1930, he came to the United States as visiting lecturer to the Institute of the History of Medicine of the Johns Hopkins University. His lectures were published in 1931 as *The Foundations of Medical History*, a small, but finely evaluated

document, particularly relating to the early history of medicine in England, a field in which he was a well-known authority. In 1931, his *Selected Writings* were issued, covering the period from 1877 to 1930. Finally, in 1939, a small book, entitled *A Mirror for Surgeons: Selected readings in surgery*, was published both in Great Britain and in this country.

D'Arcy Power was a man of great charm. He made friends readily. For years he was known to the students at St. Bartholomew's Hospital as "Sunny Jim." Although he was always cheery and never complaining, life dealt him many tragic blows. His only daughter died of whooping cough at the age of two, and his younger son was killed in World War I. During his last years he was saddened by the death of his wife. He kept up his activities, however, almost to the very end, occupying his house on Chandos Street, long a mecca for friends of medical history, throughout the bombing of London and up until the beginning of the present year. He then found it no longer safe to live there, or to keep his books, of which he had a great many, in such an exposed position. One of his last letters, stating that his books would be sold at Sotheby's auction room in London, was published in the May 17, 1941, issue of the *Journal of the American Medical Association*. A catalog of these books, recently received, shows that he had collected over the years a considerable number of important medical texts, some of which will find their way to this country.

Even in his later years, D'Arcy Power was an active person. He wrote, for example, many of the obituary notices of medical men in *The Times*, of London. This meant that he had to have the material readily at hand, for the notices were prepared in the course of a few hours. For the average man, this would have been impossible, but for the quick, surgically trained Power, nothing was too much of a task, and he turned out extraordinary obituary notes for the daily press, listing not only the important contributions that the deceased colleague had made to medicine, but also giving an estimate of the man's

character and the passing or enduring value of his work.

He kept up his cheerfulness to the end of his life. In a letter written last fall from London, before he had moved into the country, he noted in a postscript: "London has become very noisy. Fortunately, I have one deaf ear and I am not, therefore, much disturbed at night." For a man in his eighty-fifth year, living in the heart of London during the height of the blitzkrieg, to write in such a fashion characterizes this forthright gentleman. Surgeon, historian, biographer, lover of mankind, keen student of human nature, delightful correspondent and charming friend, D'Arcy Power leaves behind him many memories that will long be cherished by his friends, as well as a score of monumental contributions to medical literature. It was, indeed, characteristic of him that just before he died, he turned over to the Royal College of Surgeons a supplement to *Plarr's Lives*, bringing the necrologies up to 1940.

A fitting eulogy is contained in the final paragraph of his death notice in the May 31, 1941, issue of the *Lancet*.

And now that he has gone to his rest, he stands out not so much as a single individual, but as one of a chain of stouthearted English doctors continuing to serve mankind. For his father, coming from an old Yorkshire family, was Henry Power, the ophthalmic surgeon, a fine figure of a man. His son, D'Arcy II, is high up in the medical service of the Royal Air Force, and his grandson, D'Arcy III, is following the same profession. Here indeed is a family that have served their country well.

## MEDICAL EPONYM

### HUNTER'S GLOSSITIS

The strongly individualistic contributions of Dr. William Hunter (1861-), pathologist to the Charing-Cross Hospital, to knowledge of the nature and causes of pernicious anemia include numerous descriptions of the glossitis that is often identified by his name. The following quotation is from his article, "Further Observations on Pernicious Anaemia (Severe Cases): A chronic infective disease: Its relation to infection from the mouth and stomach: Suggested serum treatment," which appeared in the *Lancet* (1: 221-224, 296-299, 371-377, 1900):

... I was struck by the curious character of the sores on the tongue—localised inflamed patches sometimes showing vesicles filled with clear serum situated under the tip of the tongue, the inflamed areas shifting from time to time, with atrophic appearance of the intervening mucosa. The condition thus described is not one of ordinary stomatitis or glossitis such as one meets with as the result of the local irritation of decayed or irregular teeth. . . . Another feature I have had to note is what I may term the "periodicity" of the stomatitis—its variability from time to time, independently apparently of treatment, notably its greater severity at the outset of the disease, usually tending to subside or at least to give less discomfort as the disease advances.

## MASSACHUSETTS MEDICAL SOCIETY

### SECTION OF OBSTETRICS AND GYNECOLOGY\*

RAYMOND S. TITUS, M.D., *Secretary*  
330 Dartmouth Street  
Boston

#### CESAREAN SECTION, FOLLOWED BY FATAL SURGICAL SHOCK

A thirty-six-year-old primipara at term, because of fetal distress, was delivered by cesarean section when the cervix was almost fully dilated.

The prenatal care had been excellent. The patient had been under observation since the beginning of the third month, during which time the blood pressure was normal and the urine showed no albumin. At about four and a half months a large intramural fibroid was removed. This did not interrupt the pregnancy. The convalescence from this operation was stormy, and during the rest of the pregnancy the patient suffered from a secondary anemia, which was treated with ferrous sulfate and liver. The patient was in the hospital for observation several times during the last two months of her pregnancy.

Three weeks after the expected date of confinement, labor started, being induced by castor oil. Because she was rated as a bad surgical risk and because it was known that the baby was small, a test of labor was considered a conservative method of handling this particular patient. Two donors were in constant attendance during the labor, as was the physician. The labor was normal. At the end of nine hours, the cervix was practically fully dilated, with unruptured membranes. At this time, the membranes were ruptured and the head settled into the pelvis. Unfortunately, however, the

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

fetal heart became irregular and the rate slowed to about 90 beats per minute. Cesarean section was decided on, because of the irregular fetal heart and the patient's age. At operation, the cord was found to be tight about one shoulder, a condition that was probably the cause of the fetal distress. The amount of blood lost at operation was said to have been little. During operation, however, the patient's blood pressure could not be obtained and the pulse was very rapid. Intravenous glucose and 500 cc of blood were given at the end of the operation. The patient responded well but an hour later went into collapse and died.

*Comment.* Intramural fibroids that are removed during pregnancy may so injure the uterine wall that rupture during labor must be considered a possibility. Because of this, the patient was under close observation during labor, so that cesarean section could have been performed immediately, if there were any evidence of rupture.

When a patient is practically fully dilated and the fetal heart shows distress, it is always questionable whether cesarean section is a justifiable procedure. One would hesitate, knowing that the wall of the uterus had been weakened by a myomectomy, to perform a version. With full dilatation and the head in mid position, forceps in the hands of a skilled operator would probably have guaranteed a live baby about as well as laparotomy.

Shock is a peculiar thing. This patient apparently did not die of hemorrhage, but the laparotomy was more than she could stand. Everything was done that could have been done,—the patient was transfused, after which she rallied,—but in spite of this, she sank into collapse and died.

## COMMITTEE ON PUBLIC RELATIONS

It seems likely that many members of the Society would be interested in the following resolutions, which were recently passed by the medical staff of the Cape Cod Hospital and approved by its executive committee:

ELMER S. BAGNALL, *Secretary*

\* \* \*

WHEREAS, If we are not at war, we are in a state of grave emergency, and

WHEREAS, Both federal and state governments wish the regular forces strengthened by volunteers, and

WHEREAS, The enrollment of volunteers is hampered, first, by fear of personal injury and, second, by lack of measures to see that volunteers will be cared for, if injured in training or action, be it therefore

RESOLVED, That the Cape Cod Hospital and Cape Cod Hospital staff mutually agree to assure free hospitalization and medical care for any such volunteers to the limit of their resources, volunteers to be certified to have been injured in line of duty, while in training or on public service, and to include the State Guard, and be it further

RESOLVED, That should future plans or laws provide payment for such care and should payment be made for such care, the Cape Cod Hospital staff agrees to add such sums to the endowment fund of the Cape Cod Hospital.

## DEATHS

ANDERSON—BERTHA O. ANDERSON, M.D., of Pittsfield, died June 25. She was in her fifty-ninth year.

Born at Lawrence, Kansas, she received her degree from the University of Kansas School of Medicine in 1911. From 1911 to 1929 Dr. Anderson practiced general medicine, surgery and obstetrics in Lincoln, Illinois. From 1931 to 1935 she practiced in Lakewood, Ohio, specializing in diseases of the gastrointestinal tract, gynecology and proctology. She had taken postgraduate work at the New York Polyclinic Hospital and Harvard Summer School, and had done observation work at the Mayo Clinic in Rochester, Minnesota. She moved to Pittsfield in 1935 because of ill health.

Dr. Anderson was a member of the Massachusetts Medical Society and the American Medical Association. She was also a member of the National Women's Medical Association, the Women's Medical Association and the Lake Wood (Ohio) Medical Club.

A brother, a nephew and a niece survive her.

BURNETT—FRANK H. BURNETT, M.D., of Brockton, died June 21. He was in his seventy-sixth year.

Born in Guilford, Vermont, he attended Dartmouth College and received his degree from Dartmouth Medical School in 1890. Dr. Burnett was on the staff of the Brockton Hospital and was a former president of the Plymouth County Medical Society. He was a member of the Massachusetts Medical Society and the American Medical Association.

His brother survives him.

MCCROSSAN—CHARLES L. MCCROSSAN, M.D., of Somerville, died June 26. He was in his fifty-sixth year.

Born in Somerville, he attended Harvard University and received his degree from Harvard Medical School in 1910. At the time of his death he was a member of the Somerville Board of Health and was on the staff of the Somerville Hospital. He was a member of the Massachusetts Medical Society, the American Medical Association and the New England Obstetrical and Gynecological Society.

His widow, his father, a daughter, a son and two brothers survive him.

MULHOLLAND—BERNARD J. MULHOLLAND, M.D., of Lawrence, died April 16. He was in his fifty-ninth year.

Born in Lawrence, he received his degree from Biltmore Medical College in 1906, and started private practice in Lawrence.

He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow and two daughters survive him.

VICKERY—EUGENE A. VICKERY, M.D., of Wellesley, died June 22. He was in his sixty-third year.

Dr. Vickery received his degree from Harvard Medical School in 1903. He was a fellow of the Massachusetts Medical Society and the American Medical Association. At the time of his death he was Commander, Medical Corps, United States Navy (retired). He was a member of the Southeastern Surgical Congress and a fellow of the American College of Surgeons.

His widow survives him.

WALSH—JAMES H. WALSH, M.D., of Fall River, died May 14. He was in his fifty-eighth year.

Born in Fall River, he received his degree from the College of Physicians and Surgeons of Baltimore, Maryland, in 1910. He was a former president of the Fall River Medical Society, and was a member of the Advisory Board of the Union Hospital. For thirty years he was bacteriologist for the City of Fall River and was associate medical examiner for several years. For many years he was pathologist at the Union, St. Anne's and General hospitals, of Fall River, and the Newport Hospital of Newport, Rhode Island. At the time of his death he was on the Selective Service Board.

Dr. Walsh was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow, a daughter and a son survive him.

## CORRESPONDENCE

### NEW REGULATIONS IN REGARD TO COMMUNICABLE DISEASES

*To the Editor:* In 1938 an amendment to Section 6 of Chapter III of the General Laws authorized the Department of Public Health to make rules and regulations in regard to the control of communicable diseases. Such regulations were formulated and approved on August 9 of that year and were printed in the September 15, 1938, issue of the *Journal*.

In October of the same year, "infectious encephalitis" was made reportable, replacing the old terminology of "encephalitis lethargica." A note in regard to this change appeared in the November 10 issue of the *Journal*.

On May 13, 1941, further additions were made to the list of reportable diseases, and certain amendments were made in the isolation and quarantine requirements to bring them in line with the latest revision of the recommendations of the Subcommittee on Communicable Disease Control of the American Public Health Association. These changes are given below.

Printed copies of the revised regulations will be available for distribution in the very near future. The revised list of reportable diseases is also being reprinted and will be sent to every physician in the State.

I should also like to call attention to the fact that the rules and regulations for the treatment of persons exposed to rabies were amended so that the first sentence of Rule 2 reads as follows: "Antirabic vaccine and antirabic treatment shall be furnished by the board of health for all persons bitten on the head, or in cases with severe multiple lacerations." The amendment consists of the addition of the last phrase of this sentence.

PAUL J. JAKMAUH, M.D.  
Commissioner of Public Health

State House  
Boston

## CHANGES IN ISOLATION AND QUARANTINE REQUIREMENTS

### List of Reportable Diseases

Lymphocytic choriomeningitis and Weil's disease were added to the reportable list, and all forms of meningitis were made reportable. "Paratyphoid fever A and B" was changed to "Paratyphoid fever and all other *Salmonella* infections."

### Periods of Isolation and Quarantine

*Chicken pox.* (Column 2.) Amended to read as follows: "One week from appearance of eruption and thereafter until crusts have disappeared, provided that total period of isolation shall not exceed fourteen days."

*Cholecystitis of typhoid origin.* (Columns 4 and 5.) Omitted "No restrictions" and substituted "Same as typhoid fever."

*Diphtheria.* (Column 4.) Omitted "or on the basis of a previous attack of the disease."

*Dysentery, amebic.* (Column 2.) Omitted "Same as typhoid fever" and substituted "No restrictions except for foodhandlers, who shall be kept from their occupations until three successive negative stool examinations, secured at intervals of not less than three days apart, shall have been obtained." (Column 3.) Omitted "Note 3" and substituted "No restrictions except for foodhandlers, for whom restrictions are same as for case."

*Dysentery, bacillary.* (Columns 4 and 5.) Omitted "No restrictions" and substituted "Same as typhoid fever."

*Infectious encephalitis.* (Column 1.) Order of words changed to "Encephalitis, infectious," and placed in table immediately after "Dysentery, bacillary."

*Lobar pneumonia.* (Column 1.) Order of words changed to "Pneumonia, lobar," and placed in table immediately after "Plague."

*Lymphocytic choriomeningitis.* (Column 1.) Placed in table immediately after "Leprosy." (Column 2.) "Until recovery." (Columns 3, 4 and 5.) "No restrictions." (Column 6.) "No."

*Measles.* (Column 5.) Changed "Note 7" to read "Note 8."

*Meningococcus meningitis.* (Column 1.) Order of words changed to "Meningitis, meningococcal."

*Ophthalmia neonatorum.* (Column 2.) Amended to read: "One week after subsidence of symptoms. In gonococcal ophthalmia, thereafter until two successive smears from each eye at an interval of not less than forty-eight hours are negative for gonococci."

*Paratyphoid fever.* (Column 1.) Omitted "A and B" and substituted "and all other *Salmonella* infections." (Columns 4 and 5.) Omitted "No restrictions" and substituted "Same as typhoid fever."

*Pfeiffer bacillus meningitis.* (Column 1.) Amended to read: "Meningitis, other forms, such as Pfeiffer bacillus, pneumococcal, streptococcal, etc." and placed in table immediately after "Meningitis, meningococcal." (Column 2.) Omitted "No restrictions" and substituted "Until recovery."

*Tuberculosis.* (Column 3.) Omitted "No restrictions" substituted "Note 7."

*Typhoid fever.* (Columns 4 and 5.) Omitted "No restrictions" and substituted "No restrictions provided contacts can be relied upon to observe precautions outlined by board of health and provided at least one satisfactory stool specimen is submitted for examination."

*Weil's disease, infectious jaundice due to *Leptospira icterohemorrhagiae*.* (Column 1.) Placed in table imme-

diately after "Undulant fever" (Column 2) "Until recovery" (Columns 3, 4 and 5) "No restrictions" (Column 6) No"

#### Notes

**Note 3** In line 1 substituted household for "family" Omitted the words "amebic or" and substituted the word "fever" for the phrase "A or B" Added the following sentence to the note "Foodhandlers living in a household with a recovered case which continues to excrete typhoid bacilli after convalescence shall be excluded from their occupations unless they have been inoculated with typhoid vaccine within two years"

**Note 6** Amended to read "Patients with open tuberculosis should in most cases receive sanatorium treatment both for the benefit of the individual and the protection of his family Those who remain in their homes shall observe all precautions necessary to prevent infection of the members of their families and of others with whom they may come in contact This shall include approved methods of collection and disposal of the sputum the sterilization of any articles of clothing and of toilet articles which may become contaminated by the sputum the use of separate dishes and eating utensils and proper sterilization of the same The patient should sleep in a separate room For details concerning precautions in home care a pamphlet of the Massachusetts Department of Public Health entitled *Home Care of Tuberculosis Patients* is available

"As soon as a diagnosis of tuberculosis has been established arrangements should be made for the examination, including an x ray of the chest, of all members of the immediate family and of other persons with whom the patient has been in close contact If the family cannot afford x ray examination by a private physician, facilities are available through the various state, county and municipal sanatoria Persons with suspicious findings and those who have had contact with a tuberculous patient should be kept under medical observation as long as advised by the physician It is the responsibility of the local board of health to provide hospital care for cases of tuberculosis, when needed, and to see that contacts are examined where such examinations have not been made through a private physician

"When a case is reported the public health nurse representing the board of health should visit the patient's home She should instruct the family in the sanitary precautions described above, see that arrangements are made for the examination of contacts and if necessary provide transportation to the place where they are to be x rayed and should aid the patient in obtaining admission to a sanatorium if this has been recommended by his physician

"Hereafter, the nurse should make visits to the home at least once in six months to determine whether the patient has moved, whether the above mentioned precautions are still being observed and whether any new measures are needed to control the spread of the disease If the patient has moved in another town or state, the Massachusetts Department of Public Health should be notified In cases where the physician wishes to exercise complete supervision, the nurse should obtain such information from him

"The only acceptable reasons for the board of health failing to exercise the supervision outlined above are refusal of the family physician to permit periodic visits by the nurse or placing of the patient's name on an 'inactive list' as a result of examination, including x ray

"No person who has or who has had tubercle bacilli in the sputum or other bodily discharges shall be allowed

to engage in teaching, nursing, dairying or occupations involving food handling or the care of children until he has received a certificate from the board of health stating that his employment would not be dangerous to the public health"

**Note 7** Substituted "Persons living in a family in which a case of tuberculosis exists or has existed within two years, and whose occupations involve food handling or contact with children, shall be required to have an x ray of the chest to determine whether they shall be allowed to continue in such occupations"

**Note 8** Former Note 7, renumbered

## REPORTS OF MEETINGS

### HARVARD MEDICAL SOCIETY

A regular meeting of the Harvard Medical Society, held at the Peter Bent Brigham Hospital on April 8, was inaugurated by the usual presentation of a case.

A middle-aged woman had experienced a fall eight months before admission, with the subsequent development of headache and dizziness. She had had known hypertension for two years. For two weeks prior to entry, there had been extreme vertigo, with a marked tendency to stumble to the left and with weakness of the right side. Physical examination was remarkable chiefly for moderate cardiac enlargement and hypertension (160 systolic, 100 diastolic). On neurologic appraisal, there was weakness of the right arm and leg associated with diminished tendon reflexes. Poor co-ordination of the left arm and leg was noted. Pain sense was diminished on the left trunk and leg. All laboratory data, including examination of the cerebrospinal fluid, were negative. The electroencephalogram revealed diffuse abnormalities from all areas, and a cystometrogram indicated the presence of a cord bladder.

Dr. Soma Weiss stated that this was an example of an unusual syndrome, thrombosis of the inferior cerebellar artery—in this case, on the left side. This condition results in pyramidal-tract signs on the opposite side, and cerebellar and sympathetic manifestations on the homolateral side. Dr. E. A. Stead, Jr., remarked that the disease is rare in that the symptoms and signs result from central rather than peripheral paralysis. Therefore, a dissociation of symptoms, with some normal as well as abnormal responses, may result.

The speaker of the evening was Dr. Walter F. Dearborn, of Harvard University, whose subject was "Disabilities in Reading and Their Remedying." In introduction, it was emphasized that these difficulties may occur at any level of educational life and may cause late as well as early failures. A welter of causes has been suggested, which may be environmental, educational or organic. Poor training, large classes, absence from school, faulty home facilities and so forth may contribute a share of reading disability. Organic causes, such as difficulty with articulation, deviations in eye and hand dominance and anisopia, probably function largely as ini-

tial handicaps that trip only a few students, whereas multiple structural changes are frequent. Visual acuity and eye-muscle imbalance are becoming less popular as causative factors.

Dr. Dearborn believes that laterality and mixed dominance play a role. Even opponents agree that left-eye dominance favors right-to-left eye movements. Although something may be gained by waiting in such cases, Dr. Dearborn suggests "changing the menu" in the meantime to avoid the early emotional upsets that may occur during the process of expectant waiting. Furthermore, time alone will not always bring the desired results.

A study of left ocular and manual dominance indicates that persons with such findings are retarded in about 40 per cent of cases, but that the greatest degree is noted in those with mixed dominance of hand and eye. This may cause an aversion to reading if nothing is done at an early date. This aversion may be accentuated in an intelligent person who has some other special skill, and in such cases it is particularly worth while to treat left lateral or mixed dominance.

Anisometropia, with poor fusion of the images of the two eyes, causes an extra effort and makes reading a difficult task. This was present in 50 per cent of extreme cases of disability, as against 23 per cent in a control group. It is probably a factor in certain cases, therefore, but admittedly not an insurmountable one. In many cases of reading disability, one may discover a chief cause, but just about as frequently multiple well-recognized causative factors are present.

The chief remedy is to have only one capable instructor with a unity of purpose. Too many schools merely complicate matters, and no one is able properly to treat cases of reading disability, even when the diagnosis is made. The problem is most acute in the young, but is far from absent at college age. Freshman training at Harvard University is now accomplished by means of motion pictures graded for speed. It has been found possible in this way to increase the speed and accuracy of reading and to elevate the college grades as compared with controls. More recently, stress has been laid on comprehension rather than mere reading ability.

The discussion was opened by Dr. Edwin M. Cole, of Harvard Medical School. For organic disease or injury to cause aphasia the lesion must be unilateral on the dominant side. He has been impressed with the hereditary aspects of the dominance problem and the high incidence of stuttering, left-handedness and reading disability in such families.

Dr. Virgil G. Casten stated that an ophthalmologist's sole purpose in cases of reading disability should be to rule out organic eye disease, although even such seemingly serious findings as anisocoria seldom cause such difficulty of themselves.

In conclusion, Dr. Dearborn stated that anyone with reading disability can be either taught or improved if enough time and patience are employed.

### EVANS MEMORIAL LECTURE

At a Robert D. Evans Memorial Lecture at the Evans Memorial, Massachusetts Memorial Hospitals, on March 28, Dr. Allen O. Whipple, of Columbia University, discussed "Certain Splenopathies in Relation to the Vascular Bed of the Spleen." The discussion was based on 483 splenopathies observed in the Combined Spleen Clinic, of which 237 were operated on, with a mortality rate of 8 per cent.

There has been much discussion about the character of the vascular bed of the spleen, some observers considering

it an open system wherein there is no actual connection but merely a vascular bed between the arterioles and venules. The opposite view of a closed system with terminal arterioles communicating directly with the venous sinuses has been proposed, and some observers believe in a combination of the two extreme views. Between 1936 and 1938, it was considered that ample evidence was at hand to indicate that a closed system obtained under normal conditions, and that any suggestion of a vascular bed was the result of handling or improper technique. An improvement of the technical details whereby the spleen may be directly observed in its functioning physiologic state seems to contradict these previous findings, and it is now believed that this new method of refractility may make anatomic structure and physiologic function coincide. At any rate, certain positive statements can be made: the pulp spaces are the chief, if not the only, link between the arterioles and veins; these are variable in size and shape, with interconnections, their size is such that cells as well as fluid can pass through; they may dilate to several times the size of an erythrocyte or contract to almost nothing, the spaces are the only site of circulation and storage of and contact with phagocytes, serving as a means of bringing the circulating blood in contact with the pulp-space cells for phagocytosis and destruction of erythrocytes. Only a few important conditions associated with this pulp system were discussed.

In chronic microcytic hemolytic anemia, there may be a hemolysis at work, or inferior erythrocytes in the form of spherocytes, which are easily destroyed may be present. This was not debated. The importance of the spleen in this condition is proved by the effect of splenectomy. Microscopically there is engorgement of the pulp spaces with spherocytes, and the venous sinuses are collapsed by the pressure of the distended spaces. Since the spherocytes are unable to pass owing to their inflexible nature and their lack of rouleaux formation they are exposed for longer periods to any hemolyzing factor in the pulp-space walls, and are either sensitized or directly destroyed by the hemolysis. There is evidence of an enhanced fragility and of a larger number of such cells in the arterioles and pulp spaces than in the venules. This indicates that it is in these spaces rather than in the venous sinuses that the cells are in proximity with phagocytes.

Hypertensive splenomegaly, which is considered a congestive disease, is usually signified clinically as Banti's syndrome of hepatosplenomegaly. The present concept of this condition, which also includes the finding of anemia, leukopenia and gastrointestinal hemorrhages, includes many cases not originally considered by Banti and excludes some cases following the original description. This syndrome may be caused by any obstruction to flow within the portal vein but only if there is a gradual increase of portal vein pressure while the peripheral venous pressure remains essentially unchanged. The site of obstruction may be intrahepatic or extrahepatic. Sixty-eight per cent of 140 cases were directly attributable to cirrhosis of the liver. The amount of hypertension and splenomegaly is proportional to the type of cirrhosis. That due to *Schistosomum mansoni* causing the greatest degree. This can be reproduced in dogs by the injection of silica particles in the portal vein over a period of about sixteen months. Laennec's cirrhosis or periportal fibrosis causes a variable degree of hypertension and these patients are prone to succumb to liver insufficiency, the chief pathological findings being in the lobules rather than in the periportal areas. Among the extrahepatic causes of

the Banti syndrome may be mentioned a traumatic pancreatic cyst wherein operation effected a cure. In infants and children a congenital block of thrombosis may imitate the condition. Early operation should be carried out and a liver biopsy always performed, for only those without cirrhosis of the liver may be cured. No subsequent cirrhosis has been known to develop if there was none at operation, whereas patients with cirrhosis have recurrences of all manifestations. Histologically, these spleens have distended venous sinuses, diminished pulp spaces and fibrosis.

## BOOK REVIEWS

*The Head and Neck in Roentgen Diagnosis* By Henry K. Pincus MD, Eugene P. Pendergrass, MD, and J. Parsons Schaeffer, MD, PhD. 4<sup>th</sup> ed., cloth, with 1251 illustrations. Springfield Illinois: Charles C. Thomas, 1940. \$12.50.

This book is undoubtedly the best textbook of its kind in the English language. It is encyclopedic in character and is profusely illustrated with reproductions of roentgenograms, anatomic illustrations, drawings, photographs and even a few colored plates. The compilation and arrangement of such a monumental work must necessarily mean many months but years of arduous labor, and the painstaking accuracy with which the vast volume of material is presented is a tribute to the diligence and indefatigable attention of the authors. The book is a real monument to the memory of Henry K. Pincus, the senior author, who died while it was still in embryo, one stage and the major credit should go to the junior author, E. P. Pendergrass, who carried it to completion, with the help of the associate author J. Parsons Schaeffer, who has added the valuable anatomic groundwork on which the roentgenographic material is based. The book covers every conceivable method, procedure and process in roentgenography as well as the rules and precepts of diagnosis. It is important to know the methods of examination and the technical aids that can be used as well as the normal anatomic relations of each part examined. Both features are well covered.

The subject matter is unusually wide in scope, since the authors cover not only the skull and brain which alone would make quite a monograph but also the sinuses, the teeth and jaws, the mastoids, the eyes, nose and laryngeal passages and the neck—not only the cervical spine but also the soft tissues of the neck and the cervical spinal cord. It is indeed a very comprehensive and complete book and very accurate and reliable, and yet there are a few faults to be found since no book is ever quite perfect. One might grade it ninety-nine per cent and thus take away emphasis from the one per cent of criticism. The reviewer has observed only two major faults. The anatomy, although detailed and no doubt quite accurate, might well have been correlated better with the roentgenologic viewpoint and the descriptive text. As written the anatomic descriptions stand out like islands in the roentgenologic current. The other minor defect is the fact that quite a few of the illustrations were apparently made from old films or plates and are lacking in sharpness of contrast and detail such as everyone expects routinely today. This is perhaps unavoidable, since one cannot expect to accumulate perfect examples of the thousand and one varieties of disease in a year or two. The authors have wisely borrowed illustrations from their confreres and have been most careful to give due credit for each one used.

One should make particular note of the fact that all roentgenograms are printed as negatives, that is, in their original whites and blacks—a laudable procedure, and one that other roentgenologic textbooks would do well to emulate. Another very commendable feature is the extensive and complete index, covering seventy-two pages. The index of such a book must necessarily be one of its most important parts, and yet a proper index is all too frequently slighted. Not so in this book, although there are a few errors and omissions—for example, “glioma” refers only to the description of calcification in the gliomas and not to the classification of gliomas heading that section. One might add other minor criticisms, such as the charge that the authors’ classification of brain tumors as “parasellar,” “metasellar” and so forth is unclear and not useful, or that pathology and clinical correlation have been slighted for anatomy, but to do so would be to emphasize the one per cent of criticism and slight the ninety-nine per cent of commendation and approbation.

The mechanics of the book are excellent—the typography is clear, the illustrations are as good as any in American textbooks (and better than most), the paper is of very good quality, and the whole make-up is highly commendable. The publishers as well as the authors are to be congratulated. On the whole, this book is valuable, comprehensive and accurate, and should be in every roentgenologist’s office—on his desk for everyday use.

---

*De morbis artificum* [Disease of Workers]. A diatribe by Bernardini Ramazzini. The Latin text of 1713—revised, with translation and notes. By Wilmer Cave Wright. 8°, cloth, 549 pp., with 3 illustrations. Chicago: University of Chicago Press, 1940. \$5.00.

One of the classic texts of medicine is the book by Ramazzini, first published in 1700, on occupational diseases. An English translation has long been needed, for the book has not been put into that language since the eighteenth century, and at that time only part of it was translated. In many cases, moreover, the early translators paraphrased the text and omitted what they thought superfluous or obscure. Now, Dr. Wright, emeritus professor of Greek at Bryn Mawr College, and well known for her fine translation of Fracastorius’ *De Contagione* (1546), has made an excellent English translation from the Latin text of 1713. She has, moreover, added numerous notes, and provided a sixty-four-page introduction, giving not only the history of the man but details in regard to the various printings of the book itself. Such a book must naturally be in the historical collection of every medical library. The volume is one of a series issued on the history of medicine under the auspices of the Library of the New York Academy of Medicine. Not the least useful of the series of texts published under their auspices is this book by Ramazzini.

---

*Doctor in Arabia*. By Paul W. Harrison, M.D. 8°, cloth, 303 pp., with 9 illustrations. New York: The John Day Company, 1940. \$3.00.

Harrison, a graduate of Johns Hopkins, went to Arabia as a missionary doctor after finishing his internship in Boston, and settled in Muscat, on the Persian Gulf, one of the driest, hottest and most inaccessible corners of the world. Muscat was the center of the contraband traffic in ammunitions, and Harrison found a million rifles for sale in the warehouses of that little city. It was also the port

for the export of Oman dates. When Harrison set up his hospital, it is interesting to note that operation for strangulated hernia was one of the commonest.

Harrison describes his patients, the public-health problems and economic and social conditions in Oman, and the daily life of a splendid, high-minded missionary doctor, working against heavy, environmental odds. He looks forward to a time when the government of Oman will organize a health service for the whole country. This would be the only way to fight the diseases commonly met with in Dr. Harrison’s hospital: malaria, Madura foot, trachoma, syphilis, gonorrhea and leprosy. The members of the medical staff should be natives, and the hospital should be a department of the government, with community support behind it. One is convinced that Dr. Harrison had made out a case and that his book points the way to the value of social medicine in the isolated corners of the world.

---

*Manual of Physical Diagnosis, with Special Consideration of the Heart and Lungs*. By Maurice Lewison, M.D., and Ellis B. Freilich, M.D. In collaboration with George C. Coe, M.D. 8°, cloth, 317 pp., with 75 illustrations. Chicago: The Year Book Publishers, Incorporated, 1941. \$3.00.

The appearance of so many new textbooks of physical diagnosis during the last few years may be attributed to the natural desire of each publishing company to find and sell a text that will be accepted as standard all over the country. These books generally show little originality, and vary from one another only in the degree of elaboration and pictorial illustration with which they present the old facts of physical examination combined with a certain amount of electrocardiography, and the discussion of a few groups of clinical syndromes, particularly “diseases of the chest and circulatory organs.” Some of them, such as those offered by Martini, by Buck and by Clendening, limit their subject matter to the noninstrumental examination of the patient. This book is an example of the simpler type of text, and is to be recommended on this account.

There is remarkably little fault to be found in respect to its accuracy, although the old American legend of physiologic dullness of the apex of the right lung is dutifully repeated. A defect is that bibliographic references which might aid the student to develop the habit of consulting original sources are entirely lacking.

---

*Bacteriology in Neuropsychiatry: A survey of investigations concerned with the specific role of infectious and immune processes*. By Nicholas Kopeloff, Ph.D. 8°, cloth, 316 pp., with 11 tables. Springfield, Illinois: Charles C Thomas, 1941. \$4.50.

The reviewer has rarely met with a book that seems to have as slight a value to the medical profession as this one. All the material of any worth is easily found in common medical literature. The second half of the volume is padded with speculations of no apparent scientific value, and there are large sections on treatment, which seem to be wholly out of place in a book on bacteriology. The literature is widely quoted, but with little discrimination. The book, unfortunately, is finely published, and the splendid reputation of the publisher may catch the unwary.

## POLYNEURITIS WITH FACIAL DIPLEGIA\*

### A Clinical Study

FRANCIS M. FORSTER, M.D.,<sup>†</sup> MADELAINE BROWN, M.D.,<sup>‡</sup> AND H. HOUSTON MERRITT, M.D.<sup>§</sup>

BOSTON

**P**OLYNEURITIS with facial diplegia, or so-called "infectious neuritis" or "neuronitis," has attracted considerable attention since 1908, when Laurens<sup>1</sup> published his Paris thesis, entitled "*Des diplegies faciales au cours des polynévrites*."

The cause of this type of polyneuritis is obscure. Since the onset of the neuritic symptoms in many of the cases followed an upper respiratory infection, it was thought that a filterable virus might be the causative agent, but all recent attempts to isolate a virus from these cases have been unsuccessful. The pathology has not been adequately studied because until recent years the disease has been relatively benign. From the reports of the few cases that have been studied, the pathology consists chiefly of a degeneration of the myelin sheaths of the peripheral nerves, with slight changes in the axis cylinders.<sup>2-3</sup> Inflammatory reaction in the nerves may or may not be present. The central nervous system is not affected to any appreciable extent, except for swelling and chromatolysis (axonal reaction) of the motor cells in the medulla and in the ventral horns of the spinal cord.

Indeed, there is some doubt whether these cases constitute a true disease entity, since facial diplegia may be present in polyneuritides of diverse causes and absent in otherwise typical cases of infectious polyneuritis. The clinical picture is sufficiently characteristic in the majority of the reported cases<sup>2-3</sup> to justify the conviction that there must be a common etiologic factor.

Since there are few reports in the literature of large series of cases followed for any length of time, it was thought advisable to present an analy-

sis of the 26 cases that have been studied on the neurologic wards of the Boston City Hospital in the last ten years. Particular attention is given to the status of the patients who recovered, and an attempt is made to evaluate the factors in the history and the clinical findings that are significant in regard to recovery or death. A complete description of the pathological findings in the fatal cases that came to necropsy will be presented in a subsequent publication from this clinic.

A summary of the history, examination and final status of the 26 cases is given in Table 1. The complete record of two typical cases is also presented.

### ANALYSIS OF CASES

*Age and sex.* The disease is commonest in young adults or in early middle age. The extreme age limits in our series were two and seventy-eight, with an average of thirty-five years. The division of the 26 cases according to age decades was as follows: first, 2; second, 2; third, 6; fourth, 8; fifth, 5; sixth, 1; and eighth, 2.

Nineteen of the 26 patients (73 per cent) were males, and 7 were females.

*History of infection prior to onset of neuritis.* In 13 (50 per cent) of the patients, there was a history of preceding infections. An upper respiratory infection, usually of relatively mild character, had preceded the neuritis in 10 patients. In the 3 remaining patients, 1 had an acute gastroenteritis, 1 a pyelitis, and 1 a poorly defined illness characterized by epistaxis, malaise and fever. The period between the preceding infection and the onset of the neuritic symptoms varied between two and twenty-eight days. This interval was less than two weeks in 10 of the 13 cases.

*Mode of onset.* In 15 of the 26 cases the symptoms were generalized at the onset. This is somewhat contrary to the usual conception. However,

\*Decreased in arms, absent in legs.

†Improved on discharge; no follow-up made.

when the illness began with localized involvement it was predominantly in the lower extremity (10 cases).

**Temperature and pulse.** In only 5 patients was the admission temperature 100°F. or above, and in these the temperatures were 100.4, 100, 100, 104 and 102°F. The temperature usually became normal in a few days.

Pulse rates were but moderately elevated, averaging approximately 95 on admission. However, in the fatal terminations there was a rise in pulse rate. When the use of a respirator became necessary it was not unusual for the pulse to become rapid, weak and thready, frequently faster than 150 a minute.

**Cranial-nerve involvement.** The cranial nerves were involved in 22 patients (85 per cent). The facial nerve was involved on both sides in all these patients. The frequency of this involvement alone and in combination with other cranial nerves is shown in Table 2. The infrequency of

patient. The response to plantar stimulation was usually absent, or there was a slight downward flexion.

**Respiratory failure.** In 13 patients, sufficient embarrassment of respiration occurred to necessitate the use of a respirator. The interim between onset of illness and the use of the respirator varied from two to twenty-one days, with an average of twelve days.

#### LABORATORY DATA

**White-cell counts.** The white-cell counts varied from 6200 to 22,000. Counts above 10,000 were recorded in 9 out of 22 cases.

**Red-cell counts.** Red-cell counts varied from 2,900,000 to 6,000,000. Four patients had counts below 4,000,000.

**Hemoglobin.** The hemoglobin varied from 58 to 108 per cent, with an average of 89 per cent. Only 2 patients had a hemoglobin below 70 per cent.

**Urine.** Routine tests on the urine were negative in all but 5 patients; in 4 of these the urine contained a slight amount of albumin, and in 1 a large amount of albumin and a few white cells.

**Cerebrospinal fluid.** The cerebrospinal fluid was examined one or more times in all 26 patients. The figures given below are an analysis of the findings at first examination.

The pressure varied between 70 and 300 mm. of water, with an average of 140 mm. A pressure greater than 200 mm. was recorded in only 3 patients.

The cell count of the fluid was normal (less than 5 per cubic millimeter) in 14 patients. There were between 5 and 20 cells in the fluids from 6 patients. Cell counts greater than 20 were recorded in only 2 patients (40 and 150, respectively).

TABLE 3. The Protein Content of the Cerebrospinal Fluid Removed at First Puncture.

PROTEIN CONTENT mg/100 cc.	No. of Cases
6-30	3
30-45	4
45-75	3
75-200	12
200 or above	4*

\*354, 363, 399 and 720 mg

The cells present were of the lymphatic series. When cells were found in the fluids obtained at first puncture, there was a tendency for them to decrease in number with subsequent punctures.

The protein in the fluids varied from 9 to 750 mg. per 100 cc., with an average of 157 mg. The range of values found is shown in Table 3. The

TABLE 2. Involvement of the Cranial Nerves.

NERVES INVOLVED	No. of Cases

involvement of oculomotor nerves is conspicuous, being present only twice. In none of our cases was papilledema noted.

**Muscular system.** Motor weakness was marked, especially in the proximal joints of the limbs, and in most cases the upper and lower extremities were involved to an equal degree. The trunk muscles were also weak in the majority of the patients.

**Sensory changes.** Disturbance of superficial cutaneous sensation (touch, pinprick, temperature) was present in only 7 patients. This was usually of a mild degree, consisting of hypesthesia of a glove-and-stocking type in 4 patients, a hypesthesia in the lower extremities and trunk in 1 and a severer loss (anesthesia) in the entire lower extremities in 1. There was a slight or moderate diminution of vibratory sense in 5 patients, and position sense in the legs was lost in 1. Muscle tenderness was found in 8 of the 26 cases, and nerve-trunk tenderness in but 1.

**Deep reflexes.** The tendon reflexes were absent in all four extremities in 19 patients, diminished in 4 and diminished in the arms and absent in the legs in 3. Abdominal reflexes were usually absent. The Babinski reflex was not found in any

protein was within normal limits (less than 45 mg. per 100 cc.) in 7 cases, moderately increased (45 to 75 mg.) in 3 and greatly increased in the remaining 16.

Since there has been an attempt to explain the occasional presence of normal protein content on the basis of a time factor,—that is, when the puncture was performed too soon after the onset of the disease for the protein to be elevated,—the period between the onset of symptoms and the punctures was determined. For those patients with a protein below 90 mg. per 100 cc., the range was found to be from three to thirty-five days, with an average of fourteen days. Of the group with an elevated protein, the range was from two to two hundred and seventy days, with an average of twenty-eight. If the case with an interval of two hundred and seventy days is eliminated, the average for this group becomes fifteen days. There is not enough evidence to rule out this factor, but the figures suggest that the time element is of no importance.

The sugar content of the fluids was slightly decreased in 1 patient of the 14 in whom determinations were made; 9 were within normal limits, and 4 slightly increased. The lowest sugar was 39 mg. per 100 cc., the highest 168 mg. The average for the 16 was 70 mg.

The chloride content of the fluids was slightly decreased in 4, normal in 6, and slightly increased in 3 of the 13 cases in which this determination was made. The lowest chloride was 666 mg. per 100 cc., the highest 768 mg. The average was 710 mg.

There was no decolorization of the colloidal gold solution by the fluids from 5 cases, and an insignificant change was produced by those from 10. Complete or incomplete decolorization of the solution was produced by the fluid from 1 case, which gave a first-zone curve (5555432100), and by those from 8, which gave mid-zone or end-zone curves.

The Wassermann and Hinton reactions were negative in all fluids.

#### TREATMENT

In our present state of knowledge, treatment is mainly confined to supportive measures. In the recent cases, we have administered large doses of vitamin preparations, particularly vitamin B<sub>1</sub> and the vitamin B complex, which have not had any appreciable effect on the course of the disease.

The possibility of respiratory failure must always be kept in mind, and suction apparatus for the removal of mucus should be available. The pa-

tient should be placed in a respirator as soon as respirations become inadequate, as evidenced by cyanosis or labored respiration. Difficulty in administering intravenous stimulants by the usual method to patients in the respirator has led us to the injection of these drugs into the internal jugular vein. We have found this quite easy to do, since it does not interfere with the respirator and is simpler than using the external jugular vein.

To prevent contractures and to maintain the muscles as well as possible, the legs and arms should be splinted and a cradle used over the bed. When the acute stage has passed, physiotherapy—in the form of massage, heat, passive movements and exercise—is added.

If dysphagia is present, feedings should be restricted to liquid, high-calorie, high-vitamin diets, with gradual institution of semisolid and solid food as the patient's condition warrants.

#### END RESULTS

Eleven of the patients died. This gives a mortality rate of 42 per cent, which is in sharp contrast with the figures given by other authors. However, we found that of the 10 patients studied between 1938 and 1940, 8, or 80 per cent, died, whereas prior to 1937 there were 16 cases with only 3 deaths, or a mortality of 19 per cent. A striking increase in the virulence of the disease is apparent.

Eight of the 15 patients who survived were subsequently examined in follow-up studies; the remaining 7, who were improved at the time of discharge, could not be found. Of the 8, 5 had recovered completely, 1 had slight residual symptoms, and 2 had marked residual symptoms.

Those making a complete recovery did so in an average of fifty-seven weeks, with a variation from six weeks to three years. These patients have been able to resume gainful occupations, and careful neurologic examinations have revealed no abnormal findings. The patient with slight residual symptoms had been unable to walk for sixteen months without aid. After four years, he was able to return to his employment as a salesman. Careful examination of this patient revealed slight foot drop on the left, weakness of both extensor halluc muscles, some atrophy of the left thenar eminence, with minimal weakness of the extensor digitorum muscle on the left. A stocking type of hypesthesia to pinprick and touch persisted to the right ankle. Of the 2 patients with marked residual symptoms, one, in the course of three years, developed a picture suggestive of progressive muscular atrophy and the other, four years after

the illness, showed residual weakness of the left arm and both legs, with atrophy

### PROGNOSIS

In the fatal cases, the age varied from three to seventy-eight years, with an average of thirty-three years, as compared with an average of thirty-four years for the nonfatal cases, hence, age appears to have no effect on the outcome

Our series is too small to be statistically adequate, but it appears that the disease is more virulent in women, since the mortality rate for females was 72 per cent, as compared with 32 per cent for males

Eleven of the 13 patients requiring artificial respiration succumbed. This emphasizes the prognostic gravity of this complication, even though a respirator is used

The presence of an infection prior to the onset of the neuritic symptoms was not of significance, since this was recorded in 50 per cent of the entire group and in 45 per cent of the fatal cases

Loss of cutaneous sensation was found in 45 per cent of the fatal cases, a figure which is approximately the same as that for the entire group 42 per cent

There was nothing to indicate that the presence or absence of abnormalities in the cerebrospinal fluid played a role in the prognosis. There was a pleocytosis in the fluid of 1 of the fatal cases, and the average protein content of the fluids from the patients who recovered was 180 mg, as compared with 130 mg for those who died

### CASE REPORTS

**CASE 7** A 25-year-old Jewish man was admitted on January 24, 1938, with a history of a severe upper respiratory infection 3 weeks earlier. In the interim, he was able to continue in his occupation as a baker. Five or 6 days before admission, he noted pain in his legs, followed by paresthesias in all extremities and weakness that progressed so that by the time of admission he could not walk and could turn over in bed only with difficulty. On the day of admission, difficulty in swallowing solids developed.

The past and family histories were irrelevant. The temperature was 98°F, the pulse 96, and the respirations 18.

The patient was well developed and well nourished and appeared acutely ill. He was unable to swallow solids or to lift his arms or legs from the bed. There was no mental clouding. The face was masklike with a bilateral weakness, more marked on the right. The voice was thick and there was difficulty in raising saliva, which he was unable to swallow. The gag reflex was absent and the palatal movements were weak. There was moderate weakness of the trapezius and sternomastoid muscles. The weakness of the extremities was more marked at the proximal joints than at the distal ones. The trunk muscles were also weak. Sensory examination was negative,

except for a slight diminution of vibratory sense over the ankles. All deep and cutaneous reflexes were absent.

The urine contained a slight trace of albumin and an occasional hyaline cast, the red-cell count was 4,900,000 with a hemoglobin of 98 per cent, and the white-cell count was 7360 with a normal differential count. The blood Hinton reaction was negative. The spinal fluid was under an initial pressure of 90 mm of water. The fluid was clear and colorless, with 2 lymphocytes per cubic millimeter, a protein of 146 mg per 100 cc, a colloidal gold curve of 0000111000 and negative Hinton and Wassermann tests.

While he was in the hospital, the patient's course showed some variation. He became much worse, especially in regard to deglutition on the 1st day of hospitalization, but on the following day, January 25, he was somewhat improved. By January 28 he was again progressing downward and had developed diarrhea and fecal incontinence, the difficulty in raising mucus was more pronounced by January 31. On February 1 he developed paralysis of the diaphragm and was placed in a respirator, but was removed later that day. On February 3, however, he suddenly again developed respiratory paralysis and the pulse became progressively rapid, thready and weak, he became restless, disturbed, anxious, cyanotic and ashen, his pupils dilated, and he expired suddenly.

**CASE 11** A 23-year-old Italian was admitted on August 14, 1935, with a history of pain and weakness in both legs of 17 days' duration, with intermittent numbness and pain in the teeth. There was no preceding infection, but prior to entry the patient had lost weight and had had anorexia and malaise.

The family and past histories were irrelevant.

The temperature was 99°F, the pulse 100, and the respirations 20.

The patient was well developed and well nourished, and appeared to be acutely ill. There were diminished pain, touch and corneal reflexes in the right trigeminal distribution, with weakness of the right pterygoid muscles, complete peripheral facial paralysis on the right, and occasional twitching of the left side of the mouth; in addition, there was slight weakness of the right hand, and marked weakness of both legs. There were numbness and tingling of the fingers and toes, with hypsesthesia to pain and touch and to heat and cold of the glove and stocking type. Muscle tenderness was present in all extremities, and the deep reflexes were absent in the legs and left arm and diminished in the right arm. The plantar reflexes were normal.

Examinations of the urine were negative, the red-cell count was 3,920,000 with a hemoglobin of 71 per cent. Lumbar punctures showed initial pressures of from 110 to 140 mm of water, with normal dynamics. The cerebrospinal fluid was slightly yellow, it contained 44 cells per cubic millimeter and had a protein of 168 mg per 100 cc, a sugar of 53 mg, a chloride of 694 mg and a colloidal gold reaction of 0122332210. Blood Hinton and spinal fluid Hinton and Wassermann reactions were negative.

During hospitalization there was a progressive improvement, except for a slight, short-lived exacerbation early in September. The weakness of both cranial nerve and axial musculature showed considerable improvement under physiotherapy, and on November 22 the patient was discharged. On April 30, 1936, he developed a severe upper respiratory infection, with pain in the legs, and was readmitted. Examination showed residual weakness of the legs with muscular tenderness, slight impairment of po-

sition and vibration sensations and increased knee but diminished ankle jerks. Laboratory study, including lumbar puncture, was entirely negative. On June 2 the patient was discharged. Braces, which he had worn since his first discharge, still had to be applied to his legs.

The patient was last seen on February 2, 1940, in follow-up at our request. He was free of complaints, and stated that he had worn the braces for 14 months and that he was able to return to work as a salesman in August, 1938. Neurologic examination was negative.

#### DIFFERENTIAL DIAGNOSIS

Polyneuritis with facial diplegia or so-called "infectious polyneuritis" is characterized by the relatively acute onset of paralysis or marked weakness of the muscles of the extremities, trunk and face, with or without other cranial-nerve paralyses. The weakness of the extremities differs from that seen in other forms of polyneuritis in that the muscles of the proximal joints are more profoundly affected than those of the distal ones. The development of respiratory difficulty is common. The deep reflexes are lost in the extremities, but the cutaneous sensory loss is rarely severe. The only significant positive finding on laboratory study is an increase in the protein content of the cerebrospinal fluid. The chief differential problems are acute anterior poliomyelitis, encephalomyelitis and peripheral neuritis of other origin. The progressive involvement with a diffuse symmetrical paralysis and the changes in the cerebrospinal fluid are of especial value in the exclusion of poliomyelitis. Comparison of the figures for cells and proteins given above with those of poliomyelitis<sup>10</sup> shows a sharp discrepancy in the number of cells and the protein, when one considers

the duration of illness at the time of puncture. In the differential diagnosis from encephalomyelitis, the chief feature is the peripheral nature of the involvement. The relative absence of pleocytosis, as well as the high protein content, is a further aid. So far as other neuritides are concerned, the picture clinically differs from that of the alcoholic and toxic neuritides in its widespread involvement and particularly in the cranial-nerve involvement.

#### CONCLUSION

Perhaps the most important conclusion obtained from this study of 26 cases of polyneuritis with facial diplegia is that the previously held opinion that the disease always offers a good prognosis is erroneous. The mortality in recent cases has been high, and this increase in virulence is possible evidence for a virus etiology.

## CARCINOMA OF THE FEMALE BREAST\*

## Interval Report on the Results of Treatment

SIDNEY C. GRAVES, M.D.†

BROOKLINE, MASSACHUSETTS

THIS is the second report concerning the results of treatment of carcinoma of the breast from the clinic of the Free Hospital for Women.<sup>1</sup> It covers consecutive primary cases admitted to this hospital and its private wing, the Parkway Hospital, from November, 1900, to January, 1935. In each case the diagnosis has been made or confirmed microscopically, with the exception of 9 cases in which the disease was too far advanced to warrant operation. A special attempt has been made to evaluate the use of prophylactic x-radiation, that is, x-rays used either preoperatively or, for the most part, immediately following operation as a precaution against recurrence.

The treatment of choice has been a radical mastectomy, at times supplemented by x-ray therapy. By a radical operation is meant the removal of the whole breast, both pectoral muscles, with the exception of a narrow strip of the pectoralis major along the clavicle, and the axillary contents, including the deep fascia from the axillary vein to the epigastrum and from the sternum to the latissimus dorsi muscle, sparing only the long thoracic and thoracodorsal nerves. The procedure is contraindicated when the disease is known to have spread beyond the axilla; no attempt has been made to remove lymph nodes above the clavicle. It is also contraindicated if the tumor has grown into the chest wall, or if axillary metastases are fixed. It is not attempted if the patient is a really poor operative risk. A simple mastectomy, sometimes under local anesthesia, has often been resorted to in patients who are poor risks. This procedure has also been used as a palliative measure to prevent a sloughing necrotic mass on the chest wall, even though the disease has spread beyond the hope of cure. It is not upsetting, is often a great mental aid to the patient, and, in the opinion of the surgical staff, unless the disease has grown into the chest wall, gives cleaner and, for that reason, better results than x-ray alone.

## GENERAL RESULTS

All cases have been analyzed according to the five-year salvage. No case has been omitted. All patients lost or dead of any cause whatsoever have

been rated dead of cancer. At the end of five years, 138, or 36.7 per cent, of the 376 patients covered in this series were known to be alive. Of those who died, 5 were postoperative deaths, a mortality of 1.3 per cent. Pulmonary embolism, shock, diabetic coma and cerebral hemorrhage each accounted for a death. The fifth patient died while being treated with colloidal lead, which in 1928 was being tried as a therapeutic agent.‡ Before the end of five years, 5 more patients were reported to have died of causes other than carcinoma, namely, cerebral hemorrhage, heart dis-

ease, dissecting aneurysm, arteriosclerosis and monocytic leukemia. Nineteen cases (5.0 per cent) could not be traced.

Of the patients studied ten and fifteen years after admission, 16.6 and 8.9 per cent respectively, were known to be alive (Table 1). The longest postoperative interval was twenty-nine years and

‡This colored patient died of anaphylactic shock or pulmonary embolus one hour and forty five minutes after her first injection of colloidal lead, made according to the specifications of Professor Blair Bell and given twelve days after a radical mastectomy. Five other patients received similar injections of the same preparation on the same day without unusual disturbances.

\*From the Free Hospital for Women, Brookline

†Assistant in Gynecology, Harvard Medical School, assisting visiting surgeon, Free Hospital for Women

nine months. Two other patients were followed for twenty-eight years. The longer follow-ups are interesting, not so much from the percentage of people living, since many were lost or had died of other causes, but because they reaffirm that the five-year interval in breast cancer is useful merely for comparison, since 25 patients died of carcinoma or were living with recurrence between the fifth and tenth postoperative years, 12 between the tenth and fifteenth years, and 4 died of the disease more than fifteen years after treatment. One of the latter patients is noteworthy. Her original tumor was classified as one of low malignancy. Seven and twenty-five years after the first operation, large local recurrences were removed at other hospitals. Nearly twenty-six years after removal of the breast, the patient received radium at this hospital for carcinoma of the endometrium. Obesity and hypertension interdicted a hysterectomy. Death from pulmonary embolus occurred thirty-two days after a radium application and eleven days after the completion of fifteen treatments with x-rays. These treatments had been given without mishap, and the patient had been discharged in satisfactory condition.

Of the 376 patients, 9 were completely inoperable and died within one and a half years of admission.

A radical mastectomy was performed in 284 cases. Metastatic disease was found in the axilla and confirmed on microscopic examination in 159 cases; in 9 others it was unmistakably present from the description of the operation, but the lymph nodes were not sectioned. Of the patients with axillary metastases, 40, or 24.4 per cent, survived for five years; of 116 without axillary involvement, 70, or 60.3 per cent, were alive at the end of this interval.

A simple mastectomy or incomplete procedure was performed on 83 patients: on 38 as a palliative measure and on 45 because most of them were poor operative risks. Of the former, none survived five years, but of the latter, 28, or 62.2 per cent, lived the five-year span, although 10 eventually died of recurrence. These women were for the most part elderly, all but 5 being sixty years of age or more and one third being over seventy. In selected cases, simple mastectomy is of great value, but it should never supplant radical mastectomy as a routine procedure since one cannot tell whether metastatic nodules are present in the axilla until it is dissected.

One has the impression that in recent years the prognosis for carcinoma of the breast is better than formerly. Therefore, the cases have been

divided into groups, one including those seen from 1900 to 1919, inclusive, and three five-year groups—1920–1924, 1925–1929 and 1930–1934. For this purpose, corrected figures have been used. With the exception of patients dying postoperatively, since these might be considered to have died as a result of cancer, those dead of causes other than carcinoma before the end of the five-year interval have been omitted as inconclusive. Lost cases have not been included because a more careful follow-up by the social-service workers in recent years results in fewer of them, and this in itself might account for an improved figure. Thus the five-year salvage has increased from 31 to 38 to 39 to 44 per cent. Moreover, the 1930–1934 group without corrections shows better results in every respect than the large group. Of the patients in the 1930–1934 group subjected to a radical mastectomy, 67 per cent of those with early lesions lived five years, as did 29 per cent of those with lymph-node involvement. If corrected figures are used again in both the 1930–1934 group and the whole series, a comparison shows a five-year salvage of 71 per cent for the early cases in the former and 62 per cent in the latter; for the advanced cases, 31 per cent in the former and 26 per cent in the latter.

Only two obvious changes have taken place that might account for this improvement: propaganda to induce the patients to enter the hospital sooner and more frequent prophylactic x-radiation.

Early diagnosis is obviously of the greatest importance. Patients with no axillary metastases have a far better prognosis—at least twice as good—than those in whom positive nodes are found. Thirteen per cent more patients reported in less than three months from the time they had first noted trouble in the 1930–1934 group than in the 1920–1924 one. Unfortunately, an appalling number still have symptoms for a year or more before coming in for treatment. This was true of approximately one third of the 1930–1934 group. All too often metastases are found in the axilla at operation when the patient has noted a tumor for two weeks or less, and when even the surgeon does not believe that a cancer will be found when the lesion is biopsied.

#### PROPHYLACTIC X-RADIATION

An evaluation of the use of prophylactic x-radiation has been attempted. To do this, as nearly identical cases as possible must be compared. Therefore, only cases submitted to radical mastectomy have been considered, and these have been divided according to whether or not the dis-

case was found in the axillary nodes, and according to the microscopic degree of malignancy\*.

Patients were first referred for prophylactic x radiation from this hospital in 1918. In the beginning it was employed in a somewhat hit-or-miss fashion at the discretion of the surgeon, but from 1929 on it was used almost routinely.† Although the dosage varied widely in the early days, the majority of patients received between 2000 and 3000 r postoperatively, in doses of 250 to 300 r every third or fourth week until it was decided that the proper amount had been reached. In 1929 the method of irradiation changed. The majority of patients received a total of 4800 r. Treatments totaling 1600 r were given usually within 1 week, 400 r at a sitting, two treatments to the front and two to the back of the chest and lower neck on the affected side. Except in 16 patients in whom the first series was given immediately after operation, the technique was to give the first series of 1600 r postoperatively as soon as the skin

mastectomies and have been divided into advanced or early cases, depending on whether axillary metastases were present. They have further been divided into groups according to the degree of malignancy.

Except for the advanced cases in Groups I and III, the percentages were better when x ray treatment was given, but only significantly so in the early cases of Group III. The fact that there was twice as large a salvage of early cases in the high malignancy group when x radiation was given does not appear to be a coincidence, and argues against the idea that it is better to withhold x-ray therapy when no metastatic axillary nodes are found. Further, the failure of x ray treatment to improve the results in the advanced Group III cases supports the opinion that it is inadvisable to do an incomplete operation with the hope that irradiation will take care of any cancer that may be left behind.

Table 3 demonstrates the amount of prophylactic x radiation used in the preceding cases.

If all the radical mastectomies are grouped without reference to the degree of malignancy or dosage, there is a decided advantage for those receiving radiation. Thus, of the patients without

TABLE 2 Comparison of Patients Treated with Those not Treated by X Radiation

	X RAY TREATMENT GIVEN			NO X RAY TREATMENT GIVEN		
	NO OF CASES	5 YEAR SURVIVAL	PER CENT	NO OF CASES	5 YEAR SURVIVAL	PER CENT

axillary involvement, 66 per cent (corrected, 69 per cent) of those radiated were alive, as contrasted with 54 per cent (corrected 58 per cent) for those without radiation, and for the patients with advanced disease 27 per cent (corrected 29 per cent) of those radiated were alive as compared with 22 per cent (corrected 24 per cent) for those not so treated, however, equally good end results have been obtained by others without x radiation.<sup>4</sup> No serious complications have been noted from x radiation in the dosage used.

#### X-RADIATION FOR RECURRENCES

Twenty-one patients who previously had not been given x rays prophylactically were so treated for recurrent nodules. The dosage varied according to the tolerance of the patient and the reaction of the tumor. The average length of life following the institution of this form of therapy was

\*Greenough's<sup>1</sup> modification of Broder's classification for malignancy was followed as closely as possible. Of 283 patients who had a radical mastectomy 10 were in Group I or showed low malignancy, 152 in Group II and 123 in Group III. In the low malignancy group 70 per cent were known to be living at the end of five years. Of the cases in Groups II and III, 47 and 26 per cent respectively survived. As is to be expected the higher the degree of malignancy the worse the prognosis.

†Factors: target skin distance 50 cm., filter copper 0.5 mm., aluminum 1.0 mm., kV. 100, 20 by 30 cm. Before 1929 the x ray therapy was generously given by Dr. L. E. Morrison from 1929 on treatments have been given by Dr. John Meclen whose cooperation is gratefully acknowledged.

‡Since the fall of 1937 it has been customary to give all irradiation to tolerance in one long series of treatments.

two years. Only one patient survived five years, and she eventually died of cancer. In 9, or a little more than a third of the cases, the disease disappeared at least temporarily; hence, this form of therapy seems to hold the disease in check or greatly to improve the health of the patient in about 1 out of 3 cases.

RADIUM

Radium has been used as supplementary treatment in 15 of the reported cases. Well screened, it has been placed against local areas of disease. In all but one case, when it was applied to the axilla at operation, it has been used on recurrent nodules. It causes the disease to regress or temporarily disappear, but except for less systemic reaction, it has no advantage over deep x-ray therapy and does not cover so large a field.

AGE AS A PROGNOSTIC FACTOR

The age of the patient may be of interest from a prognostic standpoint. The youngest was twenty-four years old on admission, and the oldest eighty-one. Forty-three were under forty; 5 were less than thirty. These facts remind one that a tumor of the breast must not be viewed complacently because the patient is young, although the disease is predominantly one of older people. The largest five-year group (62) presented themselves be-

type. Of the 5 patients, 3 had tumors of a high degree of malignancy, and that of the survivor was of medium malignancy, which confirms this suggestion. However, if all the cases are divided into twenty-year groups, the percentage of five-year salvage for all admissions regardless of treatment or extent of the disease is 40 per cent for 43 cases twenty-four to thirty-nine years of age, 30 per cent for 201 cases forty to fifty-nine, and 43 per cent for 127 cases sixty to eighty-one. It will be noted that the poorest five-year salvage was in the middle age group. This may be partly explained by the degree of malignancy, for if the same age groups are analyzed, it is found that, in the younger group, 4 (9 per cent) were in Grade I, 18 (41 per cent) in Grade II, and 18 (41 per cent) in Grade III, and 3 were unclassified.<sup>\*</sup> In the middle age group, 5 (2 per cent) were in Grade I, 104 (52 per cent) in Grade II, and 88 (44 per cent) in Grade III; 4 were not graded. In the older age group, 7 (5.5 per cent) were in Grade I, 65 (51 per cent) in Grade II, and 50 (39 per cent) in Grade III; 5 were not classified. Among these cases, the middle age group had a slightly higher percentage of highly malignant tumors, but it is noteworthy that there was a very even distribution of tumors of high and low malignancy in each age group.

The more immature tumors, however, are malignant because they metastasize early, not because they are rapidly growing in situ. Thus, of the cases subjected to a radical mastectomy, diseased axillary nodes were found in 20 per cent of Grade I, 53 per cent of Grade II and 69 per cent of Grade III.

SUMMARY AND CONCLUSIONS

Three hundred and seventy-six cases of carcinoma of the breast have been analyzed. Thirty-six and seven-tenths per cent of all patients admitted to the hospital were known to be alive five years after treatment.

There is no criterion for absolute cure for cancer of the breast, since many patients died of carcinoma fifteen or more years postoperatively.

A radical mastectomy was performed in 284 cases. Of the patients without axillary metastases, 60 per cent were living at the end of five years, as were 24 per cent of those with axillary involvement. Prognosis has improved with the years; thus, the 1930-1934 group shows a salvage of 67 per cent for the early cases subjected to radical mastectomy, and 29 per cent for those with axillary involvement. If corrected figures are used, the percentages become 71 and 31, respectively.

A simple mastectomy was of value in poor op-

<sup>\*</sup>Twelve cases were unclassified, 9 because they were inoperable and 3 because the slides were not available.

tween the years of forty-five and forty-nine, inclusive, but each succeeding group to the age of sixty-five was nearly as large; 35 patients were over seventy years of age (Table 4).

It has been held that the younger the patient, the poorer the prognosis in carcinoma of the breast. Of the 5 patients under thirty years of age, only 1 was well at the end of five years. It has been suggested<sup>3</sup> that younger women do badly because the tumor is apter to be highly malignant, but that if the tumor is of low malignancy they do as well as older patients with tumors of the same

erative risks, there being a 62 per cent five year salvage for selected patients in whom there was no obvious metastasis at operation. This procedure should be used only in really bad operative risks, however, since it is impossible to rule out axillary metastases preoperatively.

The total operative mortality was 1.3 per cent.

The prognosis for carcinoma of the breast is improving. A combination primarily of earlier admissions and secondarily of prophylactic x-radiation is considered to be the reason. The cases in this series showed better results when radiation was given than when it was withheld.

Prophylactic x-radiation is thought to be of advantage, particularly in patients with tumors of high malignancy with no apparent axillary involvement. It seems wiser to use it routinely than on advanced cases only.

X-ray or radium therapy retards or causes the growth to disappear in about one third of the patients with recurrent disease. It seldom effects a five-year cure.

Cancer of the breast is not infrequent in young women, but is primarily a disease of elderly people.

Although the degree of malignancy is of significance in the prognosis of cancer of the breast, since highly malignant tumors tend to metastasize earlier, it is the extent of the disease at operation that is the most significant factor.

Acknowledgment is gratefully made to Dr. Oscar Zarkin for his collaboration, under the direction of Dr. Arthur T. Hertig, in reviewing the pathology of the tumors.

### THE LAW AND MENTAL DISEASE\*

WILLIAM C. CROSSLEY†

FALL RIVER, MASSACHUSETTS

THE generous invitation to address you who are in fields of specialization in the medical realm, coupled with an urge that the subject matter have reference to the law and insanity, is responsible for my appearance before you today. To dwell at length on a matter of such great importance, and about which volumes have been written, is obviously an utter impossibility. In the comparatively short time allotted, therefore, only cursory observations can be presented for your reflection.

This assembly is composed of men and women of scientific bent and training. Science savors of independence in thought and action. It has been individual exercise of this virtue that has produced so many humanitarian results. Despite great obstacles and seemingly insurmountable difficulties, even including persecution, individualistic genius, courage and perseverance have brought victory. Apropos of this suggestion, it seems fitting to make reference to the life of a man to whom finally was given the credit for a great contribution, not only to the medical profession but to the entire world. I refer to Dr. W. T. G. Morton and the anesthetic, ether.

Just as ether has properly taken its place in the realm of blessings, other great and material factors have contributed to the advancement of man. For at least one of these factors, it is my assumption that many of those here gathered have an

affectionate regard. It is a part of their daily life; it is their profession; it is their pursuit; it is their happiness. They are the medical examiners, whose main duty it is to observe and examine and to determine the cause of death.

We who love America abhor regimentation of thought and action resulting from dictatorship. It is natural that we do, for our very beings are part and parcel of the greatest fountain of government on earth, the Constitution of the United States. From it our rights flow. They are termed constitutional rights or privileges. They are not mythical prerogatives; they are fundamental and realistic. The citizen of today has been awakened from the state of indifference and is appraising more definitely and truly the national life. Governments operated as a machine concerning the destiny of which the voice of the individual has no control, individuals or coteries of persons who set up their own style of government for the present and for the sake of expediency, those who seek to conquer and who are imbued with the false doctrine that "might makes right," have at last made an impression, and it is to be hoped, an indelible one, that one is fortunate to live in "the land of the free," where democracy really means freedom under the law and where the "consent of the governed" is paramount.

The Constitution of the United States is not a paradise for the legal profession. It is not the *sanctum sanctorum* for judges and lawyers. It is the life of all Americans. Permit me to read what

\*Presented at the annual meeting of the Massachusetts Medico-Legal Society Boston May 21, 1940.  
†District attorney Southern District of Massachusetts.

many Americans have probably not yet read, the preamble to the Constitution: "We, the people of the United States, in order to form a more perfect union, establish justice, insure domestic tranquility, provide for the common defense, promote the general welfare, and secure the blessings of liberty to ourselves and our posterity, do ordain and establish this Constitution for the United States of America."

The words, "secure the blessings of liberty to ourselves and our posterity," are all-significant. They refer to you and me; they mean the medical and legal professions; they are synonymous with the doctrine of the Golden Rule. In short, we have enjoyed the right to live in our chosen sphere protected by laws passed by Congress,—the legislative body,—acting only by virtue of the authority contained in the provisions of the Constitution.

So it is in Massachusetts. We have a state constitution second to none. By virtue of its provisions, the legislature from time to time has passed various laws for our government. Of course, laws passed by the state legislature cannot be inconsistent with or antagonistic to the provisions of the Constitution of the United States or laws passed by Congress.

Massachusetts has led the way to a great extent in the passage of humanitarian laws. Labor and health laws predominate. Other states in the Union have from time to time emulated our example. The State of New York—so I was told by a late member of this society, Dr. George Burgess Magrath—through its designated representatives sought advice when the coroner's system was to be abandoned. The medical-examiner method under our law appealed to those in New York State who were experts in dealing with sudden and violent death and its causes. It is my understanding that a study of the system in Massachusetts materially helped in the molding of the new and present one in New York State.

It is my humble judgment that the manner of selecting the medical examiners in Massachusetts is the main reason for success. This is my fourteenth year in the office of district attorney. There are eleven medical examiners, besides assistants, in the district that I represent, comprising four counties. It has been my duty, under the law, to authorize them to perform autopsies. Therefore, I have been afforded an opportunity to appraise them, because of my almost continual association with them in their work. They have proved overwhelmingly a faithful and capable body of public servants.

Section 1 of Chapter 38 of the General Laws of Massachusetts provides, in part, that "the governor, with the advice and consent of the council,

shall appoint for terms of seven years able and discreet men, learned in the science of medicine, as medical examiners in and for their respective counties, and as associate medical examiners in and for their respective districts . . . , otherwise in and for their respective counties. . . ."

You can readily appreciate that the responsibility by law is vested in the governor of the Commonwealth to appoint, and that confirmation is the prerogative of the executive council.

The judges of all the courts of the Commonwealth are similarly appointed and confirmed. They enjoy a life tenure of office.

The system of judicial appointments and tenure of office in Massachusetts has been generally commended. It has not been changed, although at times it has been assailed. Therefore, it seems but fair to contend that it has worked for the common good; and this is due to the fact that the governor and the council have followed the admonition of the statute and kept faith with its provisions. So it has been with the appointment of medical examiners.

As the law provides for the care and supervision of bodies and the determination of the cause of death in the interest of justice, so the law makes provision for the living in many ways. Particularly, does the law provide through various channels and agencies for human beings who are mentally sick. It provides for the treatment of all insane, feeble-minded and epileptic persons, and all persons addicted to the intemperate use of narcotics or stimulants. Further provision is made that no county, city or town shall establish or maintain any institution for the care, control and treatment of insane, feeble-minded or epileptic persons, or to persons addicted to the intemperate use of narcotics or stimulants, or be liable for the board, care, treatment or act of any person who shall be committed into or received by any state hospital.

The Department of Mental Health, the executive of which is the commissioner of mental health, has general supervision of all public and private institutions for insane, feeble-minded or epileptic persons, or for persons addicted to the intemperate use of narcotics or stimulants, and has charge of all persons whose care is vested in the Commonwealth by law, and supervision of all other persons received into any of these institutions.

The department takes cognizance of all matters affecting the mental health of the citizens of the Commonwealth, and makes investigation of all causes and conditions that tend to jeopardize mental health, and the causes of mental disease, feeble-mindedness and epilepsy, and the effects of employment, conditions and circumstances on men-

tal health, including the effect thereon of the use of drugs, liquors and stimulants

The commissioner administers the laws relative to persons in institutions under the general supervision of the department and prepares rules and regulations for the consideration of the department

The members of the department act as commissioners of insanity, with power to investigate the question of the sanity and condition of any person who is an inmate of any institution for the insane, public or private, or restrained of his liberty by reason of alleged insanity at any place within the Commonwealth, and discharge any such person, if in their opinion he is not insane or can be cared for after such discharge without danger to others and with benefit to himself.

There are a number of state institutions under the supervision of the Department of Mental Health, including the Worcester State Hospital, Taunton State Hospital, Northampton State Hospital, Danvers State Hospital, Grafton State Hospital, Westboro State Hospital, Foxboro State Hospital, Medfield State Hospital, Monson State Hospital, Gardner State Hospital, Wrentham State School, Boston State Hospital, Walter E. Fernald State School, Boston Psychopathic Hospital, Belchertown State School and Metropolitan State Hospital. The Bridgewater State Hospital for the criminally insane is under the jurisdiction of the Department of Correction and under the control of the superintendent of the State Farm at Bridgewater. The general interest and affairs of each state hospital are managed by trustees, who, with the approval of the department, appoint and may remove a superintendent, who shall be a physician and shall reside at the hospital.

A justice of the Superior Court in any county, either of the judges of probate for Suffolk County, the judge of probate for Nantucket County and a justice or special justice of a district court, except the municipal court of the City of Boston, within his county may commit to any institution for the insane, generally speaking.

It is provided that no person shall be committed to any institution for the insane unless there has been filed with a qualified judge a certificate of the insanity of such person by two properly qualified physicians, or without an order therefor, signed by the judge stating that he finds that the person committed is insane and is a proper subject for treatment in a hospital for the insane. No physician shall make a certificate for insanity unless he makes oath that he is a graduate of a legally chartered medical school or college, that he has been in the actual practice of medicine for three years since his graduation and for three

years preceding the making of said oath, and that he is properly registered as a physician, nor unless his standing, character and professional knowledge of insanity are satisfactory to the judge. A physician who makes such certificate shall have examined the alleged insane person within five days of his signing and making oath to the certificate, shall state therein that in his opinion such a person is insane and a proper subject for treatment in a hospital for the insane, and shall present the facts on which his opinion is based. The judge may, in his discretion, issue a warrant to the sheriff or his deputy, directing him to summon a jury of six men to hear and determine whether the alleged insane person is insane.

If two physicians, qualified as heretofore stated, find a person to be in such mental condition that his commitment to an institution for the insane is necessary for his proper care or observation, he may be committed by a judge to a state hospital for a period of thirty-five days pending the determination of his sanity. Within thirty days after such commitment the superintendent of the institution to which the person has been committed shall discharge him if he is not insane, and shall notify the judge who committed him, if he is insane, the superintendent shall report the patient's mental condition to the judge with the recommendation that he be committed as an insane person, or discharged to the care of his guardian, relatives or friends if he is harmless and can properly be cared for by them. Within the thirty-five-day period, the judge may authorize a discharge as aforesaid, or he may commit the patient to any institution for the insane as an insane person, if, in his opinion, such commitment is necessary. If the judge considers additional medical testimony of the mental condition of the alleged insane person to be desirable, he may appoint a physician to examine and report thereon.

The authorities in state hospitals are authorized by law to receive and detain therein as a boarder and patient any person who is desirous of submitting himself to treatment who makes written application therefor, and who is mentally competent to make the application; and any such person who desires to submit himself for treatment may make the written application. No such person shall be detained more than three days after having given written notice of his intention or desire to leave the institution.

America is indebted to England for many contributions to its institutions of government. Magna Charta is a famous English document that was signed by King John on June 15, 1215, at a meadow, called Runnymede, on the Thames near Windsor. The king had failed to live up to cer-

tain agreements with his barons, and they threatened to make war on him unless he conceded certain rights to them by a sealed charter. He finally yielded. It contained sixty-three articles setting forth the rights and privileges of each class of citizen and specified the power that the king might assume.

Magna Charta corresponds in a rough way to our constitution. One of the most important clauses, known in history as the thirty-ninth article, declares that no free man shall be taken or imprisoned or outlawed or banished except by the lawful judgment of his peers or the law of the land. This is the basis of the jury.

We are also indebted to England for the writ of habeas corpus. The English colonists in America brought with them this priceless privilege as part of their common-law inheritance. When application is made by an attorney or any friend of the prisoner, the latter is brought into court so that the cause of his detention may be inquired into. The writ is addressed to the sheriff, marshal or other officer having the prisoner in custody. The judge inquires into the charge on which the prisoner is held, and issues an order sending him back to jail, admitting him to bail, or setting him free, as may seem proper. The writ is intended to prevent imprisonment on false or malicious charges. It is incorporated in the Constitution of the United States, which provides that the privileges of the writ shall not be suspended unless, in case of actual rebellion and invasion, the public safety may require it. The necessity of a provision like that of the habeas corpus may be understood the more readily when it is recalled that in France prisoners of state were confined in the Bastille for years or even for life. Their friends had no possible way of bringing them into court to inquire into the causes of their detention, however unjust.

The Constitution of Massachusetts provides that "the privilege and benefit of the writ of habeas corpus shall be enjoyed in this commonwealth in the most free, easy, cheap, expeditious and ample manner." In connection therewith, this remedy is commonly used in criminal proceedings, but specific provision is also made for its use in connection with insane persons, or persons alleged to be sane, whose detention or incarceration is contended to be improper by friends or interested parties.

In justice to those who have charge and supervision of the insane, as well as to the Commonwealth as an entity, I think that it may be truthfully stated that resort to the use of habeas corpus in behalf of patients in state hospitals is a rarity. It is a pleasure for me to testify that in my entire

experience, stretching over a period of approximately fourteen years, no such matter has been called to my attention officially. Furthermore, despite unfortunate happenings that have occasionally occurred in one part of the Commonwealth, not a single complaint has ever come to me for official action. It seems to me that this is another favorable commentary on the laws affecting those who are mentally sick, as well as the personnel of the Department of Mental Health, who administer the said laws.

An outstanding and conspicuously humane piece of legislation became a part of the General Laws of Massachusetts through the efforts of one of the great men in the field of psychiatry in our time. I refer to Dr. L. Vernon Briggs. In my opinion, — and my experience has been with thousands of cases, including many matters of murder, — Dr. Briggs has unselfishly and unwittingly built a monument for himself by the service that he rendered to the citizenry of this commonwealth when in the year of 1921 there was placed on the statute book a law making certain mental examinations mandatory.

Section 100A of Chapter 123 of the General Laws of Massachusetts contains the following provisions:

Whenever a person is indicted by a grand jury for a capital offense or whenever a person, who is known to have been indicted for any other offense more than once or to have been previously convicted of a felony, is indicted by a grand jury or bound over for trial in the superior court, the clerk of the court in which the indictment is returned, or the clerk of the district court or the trial justice, as the case may be, shall give notice to the department of mental diseases, and the department shall cause such person to be examined with a view to determine his mental condition and the existence of any mental disease or defect which would affect his criminal responsibility. Whenever the probation officer of such court has in his possession or whenever the inquiry which he is required to make by section eighty-five of chapter two hundred and seventy-six discloses facts which if known to the clerk would require notice as aforesaid, such probation officer shall forthwith communicate the same to the clerk who shall thereupon give such notice unless already given. The department shall file a report of its investigation with the clerk of the court in which the trial is to be held, and the report shall be accessible to the court, the probation officer thereof, the district attorney and to the attorney for the accused. In the event of failure by the clerk of a district court or the trial justice to give notice to the department as aforesaid, the same shall be given by the clerk of the superior court after entry of a case in said court. Upon giving the notice required by this section the clerk of a court or the trial justice shall so certify on the papers. The physician making such examination shall, upon certification by the department, receive the same fees and traveling expenses as provided in section seventy-three for the examination of persons committed

to institutions and such fees and expenses shall be paid in the same manner as provided in section seventy-four for the payment of commitment expenses. Any clerk of court or trial justice who wilfully neglects to perform any duty imposed upon him by this section shall be punished by a fine of not more than fifty dollars.

This law means that when a person has been before any district or municipal court in the Commonwealth and has been found probably guilty of the crime of murder, and whose case is bound over for the consideration of a grand jury because of lack of final jurisdiction in the lower court, if the grand jury indicts him for murder, it then becomes the bounden duty under law of the clerk of the Superior Court to notify the Department of Mental Health, which was formerly known as the Department of Mental Diseases. Then two psychiatrists, under the direction of the commissioner, make a mental examination of the prisoner. They also arrange with social workers to get the background of the prisoner and his family and relatives, and they make a written report, which is filed by them in the office of the clerk of court for the county where the prisoner is situated and the charge is pending.

The same procedure prevails when a presentation is made in connection with a charge of murder to a grand jury and an indictment against the defendant results. It also prevails when a person has been indicted by a grand jury for any other offense more than once, or has been previously convicted of a felony and is indicted by a grand jury, or is bound over for trial in the Superior Court.

It may be proper for me to suggest at this time that crimes are divided into three classifications: treason, felonies and misdemeanors. Treason is levying war against the Commonwealth or giving aid or comfort to enemies, and is punished by life imprisonment. A crime punishable by death or imprisonment in the state prison is a felony. All other crimes are misdemeanors.

Although it has been the duty of the clerks of the district courts in my district to report cases to the Department of Mental Health when examinations are required, generally I have arranged for a member of my staff to keep in constant touch with the police officials in the various cities and towns and masters of the several jails for the purpose of ascertaining the background of those incarcerated or those on bail awaiting grand-jury action, to determine the necessity of mental examinations. As examinations have been found necessary, communications requesting that they be made have been sent direct from my office to the commissioner of mental health.

Co-operation between the commissioner and

those designated by him to make examinations has been so complete that not only have taxpayers been saved money and the necessity of many prospective trials but the law-enforcement officials as well as the judges have been so fortified with the history and background of the defendants, in addition to the expert opinions of the psychiatrists who examined them, that the constitutional rights of individuals have been safeguarded so far as has been humanly possible, and the ends of justice well served.

This law has done more than any other to make certain that the person charged with a crime in keeping with the provision shall not go to a prison or jail if he is insane or mentally deficient, but rather to a proper institution for treatment.

The examination is made, and opinions given by specialists in mental diseases who are reputable and who are paid a very nominal sum for their services. Their opinions are not high priced ones, nor are they bought and paid for by either the defense or the Commonwealth in competitive manner. There is no incentive for deceit or color. Both sides of any controversy receive the benefit of unadorned medical facts, and as properly as can be, judgment is then predicated thereon.

If this law, or one similar to it, had been passed by a legislature in another great state not far distant from us, I am quite sure that a travesty on justice would have been precluded. It must be true that both the defendants and the states in many other jurisdictions have been irreparably damaged and unjustly treated by the absence of such a legal provision.

It is my hope that in the early future a provision may be incorporated in Section 100 A giving to the authorities a similar jurisdiction over misdemeanors. I believe that people who commit a series of misdemeanors are many times suffering from some mental disturbance or weakness. Because the law does not make mandatory examinations in connection with misdemeanors, miscarriages of justice must on occasions result. To be sure, whenever a question is raised about the sanity or mental status of a person, the court has full power to order an examination, even in the case of a misdemeanor. Likewise, whenever I have wondered about the advisability of a mental examination, the defendant has been given the benefit of the doubt and an examination has been provided. In short, when examinations are made mandatory by law, defendants get the benefit as a matter of routine; but where there is no mandate, justice is often dependent on the exercise of discretion.

I shall mention one more matter that is of vital importance in the realm of law having to do with mental disease. It is referred to as criminal

responsibility. Criminal responsibility means liability to legal punishment. The law assumes that every person, except those in certain exempted classes, possesses the ordinary human faculties—power to choose between right and wrong and to do or refrain from doing what the law commands. The criminal law sets up certain standards of human conduct, and expects conformity therewith. As Justice Oliver Wendell Holmes, Jr.,<sup>1</sup> has said, speaking of these standards of conduct:

They do not merely require that every man should get as near as he can to the best conduct possible for him. They require him at his own peril to come up to a certain height. They take no account of incapacities, unless the weakness is so marked as to fall into well-known exceptions, such as infancy or madness. They assume that every man is as able as every other to behave as they command. If they fall on any one class harder than on another, it is on the weakest. For it is precisely to those who are most likely to err by temperament, ignorance, or folly, that the threats of the law are most dangerous.

At common law, and to a great extent the common law of England has been our heritage, a child under the age of seven years is conclusively presumed incapable of entertaining criminal intent and cannot commit a crime. Between the ages of seven and fourteen the child is presumed to be incapable, but the presumption may be rebutted. After the age of fourteen, he is presumed to have sufficient capacity, and must affirmatively show the contrary.

The ground of an infant's exemption from criminal responsibility for his acts is the want of sufficient mental capacity to entertain the criminal intent that is an essential element of every crime. When a child has reached the age of fourteen, he is presumed capable of committing crime; and to escape responsibility, he must affirmatively show want of capacity. In earlier years these rules were so harshly applied that in England a boy of ten years, who, after killing a little girl, hid her body, was held criminally liable because the circumstances were judged to show a responsible discretion; and a boy of eight years was hanged for arson. In this country, a boy of twelve has been hanged for murder.

Generally speaking, the common-law rules regarding the criminal responsibility of children have been re-enacted in the statutes. In a few states the age of incapacity has been raised by statutes, and in some the age at which presumption of capacity begins has been lowered.

Since the beginning of the twentieth century a new body of law, although not designed to supersede the criminal law on the subject, has had the practical effect of almost completely dispos-

ing the criminal courts of jurisdiction of crime committed by infants. In practically every state, laws have been passed creating juvenile courts, defining juvenile delinquency, providing administrative procedures for determining delinquencies, and for the care, treatment and discipline of delinquent children. This new development has resulted from an unwillingness to apply to children the arbitrary standards of conduct set up by the criminal law or to require of them the same conformity that is required of adults. Its effect is to extend greatly the idea of incapacity of children to commit crime, which the common law has always known. In this commonwealth, I recall the case of Jesse H. Pomeroy, who, a boy of fourteen years and five months at the time of the offense, was tried on an indictment of murder of Horace R. Millen, a child four years old, committed at Boston on April 22, 1874. The jury returned a verdict of guilty of murder in the first degree.

As in cases concerning infants and liability for crime, so in matters having to do with alleged insane persons, criminal responsibility must be determined. In the case of *Commonwealth vs. Abner Rogers, Jr.*,<sup>2</sup> Chief Justice Shaw of the Supreme Judicial Court said:

In order to constitute a crime, a person must have intelligence and capacity enough to have a criminal intent and purpose; and if his reason and mental powers are either so deficient that he has no will, conscience or controlling mental power, or if, through the overwhelming violence of mental disease, his intellectual power is for the time obliterated, he is not a responsible moral agent, and is not responsible for criminal acts.

But these are extremes easily distinguished and not to be mistaken. The difficulty lies between these extremes, in the cases of partial insanity, where the mind may be clouded and weakened, but not incapable of remembering, reasoning and judging, or so perverted by insane delusion, as to act under false impressions and influences. In these cases, the rule of law, as we understand it, is this: a man is not to be excused from responsibility, if he has capacity and reason sufficient to enable him to distinguish between right and wrong, as to the particular act he is then doing; a knowledge and consciousness that the act he is doing is wrong and criminal, and will subject him to punishment. In order to be responsible, he must have sufficient power or memory to recollect the relation in which he stands to others and in which others stand to him; that the act he is doing is contrary to the plain dictates of justice and right, injurious to others, and a violation of the dictates of duty.

The matter of criminal responsibility is left for determination by the jury that hears the particular case. Expert opinion may be given as to the state of mind of the defendant at the time an alleged criminal act was committed. Even the family

history and mental condition both before and after the act may be fully inquired into and introduced as evidence. But the question is not to be finally settled by medical science or by legal definition from the bench, although each may be of material assistance to a jury. It is the duty of the judge to state clearly and sufficiently what the jury must decide by a careful discrimination between the law and the facts that are founded on the evidence. The defendant, even if abnormally deficient in will power and of retarded mental development, can be found to be fully conscious of the criminal character and the consequences of his act. It is also a pure question of fact for the jury to decide whether the defendant is so mentally diseased that he felt impelled to act by a power that overcame his reason and judgment and was irresistible. In the final analysis, however, the jury is legally obliged to determine the defendant's responsibility by ascertaining his state of mind at the time of the commission of the act.

In the case of *Commonwealth vs. Cooper*,<sup>1</sup> the defendant was convicted of the crime of murder in the first degree by a jury. The case was taken by the defendant to the Supreme Judicial Court for a final determination on questions of law. The defendant had asked the judge in the trial court to tell the jury that if the defendant had a mental disorder called "constitutional inferiority," and if the jury found that such a disorder carried with it a diminished degree of responsibility for the act, he could not be found guilty of murder in the first degree. The judge refused to give the requested ruling. The Supreme Judicial Court sustained the trial judge's position, commenting that from the evidence—even though the consensus of the alienists, based on the defendant's family history and their examinations, classified him as constitutionally defective, or possessed of weak and diminished will power and self-control—they were not agreed that he lacked sufficient capacity to distinguish between right and wrong.

Quoting again from the case of *Commonwealth vs. Rogers*, the working rule for the guidance of the jury is summed up in the following words:

If then it is proved, to the satisfaction of the jury, that the mind of the accused was in a diseased and unsound state, the question will be, whether the disease existed to so high a degree, that for the time being it overwhelmed the reason, conscience and judgment and whether the prisoner, in committing the homicide acted from an irresistible and uncontrollable impulse. If so, then the act was not the act of a voluntary agent, but the involuntary act of the body without the concurrence of a mind directing it.

In a comparatively recent case, *Commonwealth vs. Charles Trippi*,<sup>4</sup> which involved a murder and in which the jury returned a verdict of first degree on January 23, 1929, the defendant, twenty-two years of age, was serving a sentence of fifteen to eighteen years in a Massachusetts state prison. Armed with a loaded revolver and thirty or forty extra cartridges, he made an attempt to escape from the prison, during which he shot and killed Frederick Pfluger, a guard of the institution. Certain evidence was offered by counsel for the defendant to establish that the latter's mental age was about thirteen years, as determined by psychometric tests in which event it was contended that the judge should instruct the jury that he was presumed to be incapable of forming a criminal intent. The judge ruled as follows: "I now rule that the showing, if it can be shown, that the defendant was mentally thirteen years of age, as established by the psychometric tests, does not entitle him to the benefit of the presumption claimed by counsel. Having made that ruling, I exclude this evidence on that ground." The Supreme Judicial Court upheld the ruling of the trial judge and said in part:

Criminal responsibility does not depend upon the mental age of the defendant nor upon the question whether the mind of the prisoner is above or below that of the ideal or of the average or of the normal man, but upon the question, whether the defendant knows the difference between right and wrong, can understand the relation which he bears to others and which others bear to him and has knowledge of the nature of his act so as to be able to perceive its true character and consequences to himself and to others.

I have purposely dwelt at length on the matter of criminal responsibility because my experience has taught me, particularly in murder cases, that the matter is a vexatious problem for the jury. Moreover, it is a cause for grave concern with courts, psychiatrists and district attorneys. I know that some alienists have considerable disaffection for the legal test of criminal responsibility. However, it appears to have been the fundamental test throughout judicial history, and whether a change will ever take place remains for future determination.

## COMPARATIVE COSTS OF VITAMIN C IN FRESH AND COMMERCIALY CANNED FRUIT AND VEGETABLE JUICES\*

ARTHUR D. HOLMES, PH.D.,† MADELEINE G. PIGOTT, B.S.,‡ AND FRANCIS TRIPP, M.S.§

STONEHAM, MASSACHUSETTS

SCURVY has been known on this continent for at least four centuries, or since the days when the French explorer, Jacques Cartier, and his crew were cured of scurvy by tea made from young pine buds and pine needles by a group of friendly Indians.<sup>1</sup> At that early time and for many subsequent years, little was known concerning the material that was present in plants, growing buds, fruits and vegetables and was effective in the prevention or cure of scurvy. Hence it remained for the modern scientists Waugh and King<sup>2</sup> and Svirebely and Szent-Györgyi<sup>3</sup> to isolate the antiscorbutic vitamin from orange and lemon juices and thus pave the way for the rapid progress of recent years.

Tillmans, Hirsch and Hirsch<sup>4</sup> reported a simple method for the determination of vitamin C, which is based on the reduction of 2,6-dichlorophenolindophenol or 2,6-dichlorobenzeneindophenol in acid solution. Many investigators have used this method for determining the amount of vitamin C in both fresh and canned fruit and vegetable juices. A summary of their results was published by Daniel and Munsell<sup>5</sup> and by Fixsen and Roscoe.<sup>6</sup> These writers have prepared excellent bibliographies of the extensive published reports concerning the effect of variety, maturity, soil, season, storage conditions, canning processes and other factors on the vitamin C content of both fresh and canned vegetable and fruit juices.

Since that time other reports concerning the vitamin C content of citrus fruits and vegetables have appeared in the literature—notably those by Metcalfe, Rehm and Winters,<sup>7</sup> MacLinn and Fellers,<sup>8</sup> the Council on Foods of the American Medical Association,<sup>9</sup> Floyd and Fraps,<sup>10</sup> Bessey,<sup>11</sup> Ingalls,<sup>12</sup> McElroy and Munsell,<sup>13</sup> Beacham and Bonney,<sup>14</sup> French and Abbott,<sup>15</sup> DeWitt and Sure,<sup>16</sup> Fellers,<sup>17</sup> Roberts,<sup>18</sup> Richardson, Davis and Sullivan<sup>19</sup> and Harding, Winston and Fisher.<sup>20</sup> However, in spite of the voluminous data, Olliver<sup>21</sup> and Hawley<sup>22</sup> appear to be the only investigators who have reported the comparative costs of vitamin C from natural sources.

Since the economic status of many patients has

to be considered by the physician when prescribing for dietary deficiencies, and since knowledge of the cost of vitamin C from the natural fruit and vegetable sources should be of considerable interest to many large institutions, it seemed desirable to conduct a study to determine the costs of vitamin C from fresh and commercially canned fruit and vegetable juices purchased on the open market.

### PROCEDURE

The oranges, grapefruit and lemons used in this study were bought on the open market from retail stores in Boston and its vicinity. Five different brands of Florida oranges were selected, but only one brand of the California oranges could be procured. Several unidentified brands of oranges were purchased for comparison with the oranges of known identity. The grapefruit were from Florida and Texas, and the lemons were of California origin.

The vitamin C determinations were made on the juices extracted from individual fruits, with the exception of nine samples of orange juice each of which represented the composite juices of several oranges of a single purchase of a given brand. The juice was expressed with a glass fruit reamer and strained through a light cotton 14-mesh strainer to remove seeds and pulp.

The vitamin C determinations were made by combining 2 cc. of the strained juice with 20 cc. of 8 per cent acetic acid in a 50-cc. Erlenmeyer flask and adding the dye solution|| from a microburette until a drop produced a faint-pink end point that remained for at least thirty seconds.

Since exact knowledge concerning the daily human requirements for vitamin C is lacking, and since Olliver,<sup>21</sup> Hawley<sup>22</sup> and others have tentatively assumed 50 mg. as the normal daily requirement for vitamin C, this figure has been used as the basis of computation in the present study.

### FRESH FRUIT JUICES

The results of analyses of freshly extracted orange, grapefruit and lemon juices are reported

to provide the daily vitamin C requirement of 50 mg. and the cost of this quantity of vitamin C daily. Similar data concerning the canned juices are reported in Table 2.

contained from 41 to 64 mg. of vitamin C per 100 cc. of juice. From 78 to 122 cc. of juice was required to supply 50 mg. of vitamin C at a cost of from 2.0 cents to 4.4 cents. These variations

are in accord with the reports of several investigators. Daniel, Kennedy and Munsell<sup>24</sup> in a study of Florida oranges found 45 to 51 mg. of vitamin C per 100 cc. of juice. Beacham and Bonney<sup>14</sup>

state that citrus fruits show considerable variations due to geographic location, varieties and root-stock differences. French and Abbott<sup>15</sup> in a recent study of Florida citrus fruits and vegetables reported that large variations in vitamin C content can be

expected between different varieties of citrus fruits and among samples of one variety. They also found that individual trees produced fruit the vitamin C content of which varied but slightly. Harding, Winston and Fisher<sup>20</sup> in a study of Florida oranges found higher vitamin C values for oranges picked from outside branches of the tree and well exposed to sunlight than for oranges from the interior of the tree.

The Council on Foods of the American Medical Association<sup>25</sup> reported that juice prepared from fresh Florida oranges by reaming and straining through cheesecloth contained an average of 37 mg. of vitamin C per 100 cc. They also found that orange juice maintained in stoppered flasks retained 97.6 per cent of its vitamin C activity after twenty-four hours at refrigerator temperature, and concluded from this evidence that fresh orange juice loses very little vitamin C potency on standing in the refrigerator, especially if protected from air. Ingalls<sup>12</sup> stated:

Oxidation of ascorbic acid in orange, tomato and pineapple juices proceeds so slowly at icebox temperatures that the greater part of their vitamin C potency is retained after one or two days' refrigeration. The longer they stand, however, the greater is the destruction of the vitamin. Although the rate of oxidation is materially increased at room temperatures, and greatly increased by boiling, it is not enough to necessitate particular caution in the ordinary kitchen handling and preparation of these juices.

The California oranges varied from 107 to 278 gm. in weight, and cost from 18 to 50 cents a dozen. They supplied from 44 to 126 cc. of juice, which contained from 32 to 59 mg. of vitamin C per 100 cc. From 85 to 156 cc. of juice was required to supply 50 mg. of vitamin C at a cost of from 3.2 to 7.4 cents. Richardson, Davis and Sullivan<sup>19</sup> reported that California, Valencia and navel oranges supplied from 37.5 to 52.5 cc. of juice and from 20 to 31 mg. of vitamin C per orange. Metcalfe, Rehm and Winters,<sup>7</sup> in a study of six brands of Texas oranges, found the vitamin C content per 100 cc. of juice to vary between 36.6 mg. for navel oranges to 62.3 mg. for a variety known as pineapple oranges. Floyd and Fraps,<sup>10</sup> in an extensive study of the vitamin C content of 217 samples of Texas foods, found that oranges contained from 29 to 46 mg. of vitamin C per 100 gm.

The seven oranges of unknown brand and source varied in weight from 111 to 183 gm., and cost from 18 to 35 cents a dozen. They supplied from 55 to 90 cc. of juice per orange, which contained from 27 to 52 mg. of vitamin C per 100 cc. From 96 to 185 cc. of juice was required to supply 50 mg. of vitamin C at a cost of from 2.4 to 5.9

cents Hawley,<sup>22</sup> Bessey<sup>11</sup> and Ingalls<sup>12</sup> report that fresh orange juice contains about 50 mg of vitamin C per 100 cc, but Daniel and Rutherford<sup>26</sup> found 32 to 62 mg of vitamin C per 100 cc of juice for eight varieties of oranges.

The average values for the Florida oranges were 175 gm in weight, 24 cents a dozen, 75 cc of juice per orange, 52 mg of vitamin C per 100 cc of juice; 98 cc of juice supplied 50 mg of vitamin C at a cost of 27 cents. The values for California oranges were 180 gm in weight, 32 cents per dozen, 77 cc of juice per orange, 43 mg of vitamin C per 100 cc of juice, 122 cc of juice supplied 50 mg of vitamin C at a cost of 42 cents. The averages for the oranges of unknown source were 151 gm in weight, 26 cents per dozen, 73 cc of juice per orange, 41 mg of vitamin C per 100 cc of juice, 127 cc of juice supplied 50 mg of vitamin C at a cost of 37 cents. Oliver,<sup>21</sup> an English investigator, found that 50 mg of vitamin C in orange juice cost 2½ pence, Hawley<sup>22</sup> reports the cost as 35 cents.

### *Grapefruit*

The Florida grapefruit varied from 423 to 641 gm in weight and cost from 60 cents to \$1.00 a dozen. They supplied from 175 to 230 cc of juice, which contained from 39 to 48 mg of vitamin C per 100 cc of juice. From 104 to 128 cc of juice was required to supply 50 mg of vitamin C at a cost of from 35 to 55 cents.

The Texas grapefruit varied from 418 to 455 gm in weight, all cost \$1.00 a dozen, and contained from 133 to 174 cc of juice. The juice contained from 56 to 65 mg of vitamin C per 100 cc of juice. From 77 to 89 cc of juice was required to supply 50 mg of vitamin C at a cost of from 42 to 48 cents. Olliver<sup>23</sup> states that 50 mg of vitamin C in fresh grapefruit juice costs 4½ pence, and Hawley<sup>22</sup> found the cost for this amount of vitamin C to be 35 cents.

The average values for grapefruit were 510 gm in weight, 96 cents per dozen, 185 cc of juice, 48 mg of vitamin C per 100 cc of juice, 106 cc of juice supplied 50 mg of vitamin C at a cost of 46 cents.

### *Lemons*

The lemons, all from California, varied from 106 to 155 gm in weight, cost 40 cents a dozen and supplied from 32 to 66 cc of juice, which contained from 33 to 55 mg of vitamin C per 100 cc of juice. From 91 to 151 cc of juice was required to supply 50 mg of vitamin C at a cost of from 54 to 157 cents. Richardson, Davis and Sullivan<sup>19</sup> found an average of 49 mg of vitamin C per 100 cc in California lemons. Lund, Spur

and Friderici<sup>27</sup> report that the vitamin C content of lemon juice varied from 39 to 56 mg per 100 cc. Olliver<sup>23</sup> found that 50 mg of vitamin C in lemon juice cost 3¼ pence.

The average values for lemons were 129 gm in weight, 40 cents per dozen, 55 cc of juice and 47 mg of vitamin C per lemon; 107 cc of juice supplied 50 mg of vitamin C at a cost of 70 cents.

### *CANNED FRUIT AND VEGETABLE JUICES*

The canned tomato, orange, grapefruit, lemon and pineapple juices and a series of five less important fruit juices were purchased from retail stores in Boston and its vicinity. That the data obtained might be of fairly general application, thirteen brands of tomato juice, seven brands of orange juice, twelve brands of grapefruit juice, five brands of lemon juice and seven brands of pineapple juice were assayed. Since there was a wide range in size of containers and cost for the individual canned fruit juices, no attempt was made to correlate prices with the volume of juice per can. The canned fruit juices were not strained, but the canned tomato juices were centrifuged for ten minutes at 1300 r.p.m. or until a clear yellow supernatant liquid appeared. A 5 cc portion of the supernatant layer was used for assay, instead of the 2 cc portion that was used in the assay of the fresh fruit juices.

#### *Tomato Juice*

The thirteen samples of canned tomato juice varied in vitamin C content from 8 to 21 mg, and averaged 14 mg of vitamin C per 100 cc. The amount of juice necessary to provide 50 mg of vitamin C varied from 238 to 625 cc, with an average of 368 cc. The cost of 50 mg of vitamin C in tomato juice varied from 38 to 106 cents and averaged 63 cents, a figure that is materially higher than the 475 cents reported by Hawley.<sup>22</sup>

Ingalls<sup>12</sup> stated that canned tomato juice contains 17 mg of vitamin C per 100 cc, which is in close agreement with 14 mg of vitamin C per 100 cc found in this study. A series of 132 cans of commercially canned tomato juices tested by McElroy and Munsell<sup>11</sup> averaged 17 mg per 100 cc of juice. McClinn and Fellers<sup>8</sup> have published an excellent bulletin, which reports in great detail the vitamin C content of tomatoes and tomato products as affected by such conditions as canning, storage, maturity, fertilizers and many other factors. They found that commercial brands of tomato juice contained from 7 to 18 mg, with an average of 11 mg of vitamin C per 100 cc of juice. Tressler and Curran<sup>28</sup> found that little or no loss of vitamin C occurred at the end of forty

days' storage of tomato juice in either bottles or cans completely filled with hot juice.

### *Orange Juice*

The vitamin C content of the canned orange juices varied from 31 to 54 mg., and averaged 41 mg. per 100 cc. The juice required to provide 50 mg. of vitamin C varied from 93 to 161 cc., and averaged 125 cc. The cost of 50 mg. of vitamin C in canned orange juice varied from 2.1 to 3.6 cents and averaged 2.7 cents; this figure is only a little over half the cost reported by Hawley,<sup>22</sup> who states that 50 mg. of vitamin C in canned orange juice cost 4.25 cents. Mack, Fellers, MacLinn and Bean<sup>23</sup> found 37.7 mg. of vitamin C per 100 cc. for canned orange juice.

### *Grapefruit Juice*

The vitamin C content of the canned grapefruit juice varied from 18 to 37 mg., with an average of 31 mg. per 100 cc. The juice required to provide 50 mg. varied from 135 to 278 cc., with an average of 167 cc. The cost of 50 mg. of vitamin C varied from 1.7 to 4.9 cents and averaged 3.1 cents, which is in fairly close agreement with 2.8 cents reported by Hawley.<sup>22</sup> Roberts,<sup>18</sup> in a study of the keeping qualities of vitamin C in canned grapefruit juice, found an average loss of 25 per cent at the end of nine to fifteen months. Bessey<sup>11</sup> stated that canned grapefruit and orange juices are about 70 to 90 per cent as potent in vitamin C as the fresh juice, and like most canned products remain stable while unopened but slowly lose their vitamin C when left open to the air. Fellers and Isham<sup>30</sup> reported that commercially canned orange juice, orange slices, grapefruit juice and grapefruit slices after nine months' storage contained fully as much vitamin C as fresh fruits.

### *Lemon Juice*

The vitamin C content of canned lemon juice varied from 21 to 45 mg., and averaged 36 mg. per 100 cc. The volume of juice necessary to provide 50 mg. of vitamin C varied from 111 to 238 cc., with an average of 151 cc. The cost of 50 mg. of vitamin C in canned lemon juice varied from 3.4 to 14.6 cents, and averaged 8.6 cents.

### *Pineapple Juice*

The vitamin C content of seven samples of pineapple juice varied from 7 to 13 mg., with an average of 9 mg. per 100 cc. These figures are in accord with those published by Ingalls,<sup>12</sup> who also found an average of 9 mg. of vitamin C per 100 cc. The volume of juice necessary to provide 50 mg. of vitamin C varied from 385 to 714 cc., with an average of 568 cc. The cost of 50 mg. of vitamin

C in pineapple juice varied from 7.2 to 16.9 cents, and averaged 13.0 cents.

### *Miscellaneous Juices*

Samples of canned papaya nectar, lime juice, apricot nectar, apple juice and cranberry juice were assayed for their vitamin C content. Even though most of these juices are not of commercial interest as sources of vitamin C, it is interesting to note that some of them are almost devoid of vitamin C. Their vitamin C content per 100 cc. of juice varied from 1 mg. for canned apple and cranberry juices to 22 mg. for canned lime juice. The amount of juice required to supply 50 mg. of vitamin C varied from 227 cc. of lime juice to 5000 cc. of apple and cranberry juices. The cost of 50 mg. of vitamin C in these juices varied from 19.2 cents for papaya nectar to 158.5 cents for cranberry juice.

### SUMMARY AND CONCLUSIONS

Since a number of investigators have tentatively assumed that 50 mg. of vitamin C represents the normal daily human requirement, the cost of vitamin C from the fresh and canned fruit and vegetable juices has been estimated on that basis. The average amounts of juices required to supply 50 mg. of vitamin C, arranged in ascending order, are as follows: 106 cc. of fresh grapefruit juice, 107 cc. of fresh lemon juice, 116 cc. of fresh orange juice, 125 cc. of canned orange juice, 151 cc. of canned lemon juice, 167 cc. of canned grapefruit juice, 368 cc. of canned tomato juice and 568 cc. of canned pineapple juice. The average amounts of vitamin C per 100 cc. were found to be 48 mg. for the fresh grapefruit juice, 47 mg. for fresh lemon juice, 45 mg. for fresh orange juice, 41 mg. for canned orange juice, 36 mg. for canned lemon juice, 31 mg. for canned grapefruit juice, 14 mg. for canned tomato juice and 9 mg. for canned pineapple juice.

The average cost of 50 mg. of vitamin C from the various sources under consideration was found to be 2.7 cents for canned orange juice, 3.1 cents for canned grapefruit juice, 3.7 cents for fresh orange juice, 4.6 cents for fresh grapefruit juice, 6.3 cents for canned tomato juice, 7.0 cents for fresh lemon juice, 8.6 cents for canned lemon juice and 13.0 cents for canned pineapple juice.

Since vitamin C is stored in the body for only short periods of time, a constant supply is necessary for the promotion of good health. In this study the average cost per year for a daily supply of 50 mg. of vitamin C from the various sources under consideration has been calculated as \$9.86 for canned orange juice, \$11.32 for canned grapefruit juice, \$13.51 for fresh orange juice, \$16.79 for

fresh grapefruit juice, \$23.00 for canned tomato juice, \$25.55 for fresh lemon juice, \$31.39 for canned lemon juice and \$47.45 for canned pineapple juice.

## MEDICAL PROGRESS

### PHARMACOLOGY

G. PHILIP GRABFIELD, M.D.\*

BOSTON

IN reviewing the pharmacologic literature for 1940-41, one is struck by the stream of basic research that has continued through the past few years. Some of this has been fruitful; other lines have led to conclusions that will be long delayed in practical application. The most valuable practical developments have, of course, been in the study of the sulfonamide drugs. Although they are not directly concerned in this report, it is pertinent to include certain theoretical observations, which may have clinical bearing. Of great importance in this connection is the inhibitory effect of *p*-aminobenzoic acid on the bacteriocidal action of sulfone compounds. Two phases of this action, which seem indubitably established, are worth emphasis.

First, from a theoretical point of view, it is interesting to call attention to the fact that this

inhibiting substance has been recently identified as a part of the vitamin B complex. Offhand, this suggests that excessive amounts of this vitamin might conceivably interfere with the efficacy of these drugs. In these days of indiscriminate exhibition of vitamin substances, this warning may not be so absurd as it sounds at first hearing.

The second matter of practical interest in relation to this inhibition lies in another chemotherapeutic triumph that is often neglected. It has been shown that local anesthetics of the procaine series contain this grouping and, indeed, that it is necessary for local anesthetic effects to be manifest in members of this series of drugs. The conclusion is inescapable, and the actual observation has been made, although not yet published, that the use of large quantities of local anesthetic agents containing the *p*-aminobenzoic acid grouping is contraindicated under circumstances in which interference with the action of sulfonamide drugs is undesirable. This thought must not be carried too far, since local anes-

All articles in this series will be published in book form the current volume is *Med Cal Progress Annual 1940* (Springfield, Illinois: Charles C Thomas Company 1941) \$4.00.

\*Associate in medicine and pharmacology, Harvard Medical School; senior associate in medicine, Peter Bent Brigham Hospital.

thetics are rapidly excreted, but presumably some degrees of inhibition of sulfonamides could operate for twenty-four hours after the use of such substances, and it is not difficult to think of situations in which even this effect would be undesirable.

Work reported in previous reviews on the action of various sympathomimetic drugs continues, without reaching any very certain conclusions. It is increasingly evident, however, that changes in chemical configuration in substances related to epinephrine may alter certain actions without affecting others or may affect various ones in opposite directions. It is essential, therefore, to realize the possibility of undesirable side actions in new members of this series that may come on the market. An excellent review of this subject so far as it relates to amphetamine is that of Cameron and Kasanin,<sup>1</sup> who rightly point out that many of the so-called "sympathomimetic amines" do not really possess this action in toto but only some parts of it.

The digitalis question is still the main preoccupation of certain pharmacologic laboratories. Investigations have been concerned largely with criteria of potency. These are ultimately designed to predict potency in man. As Gold and his co-workers<sup>2</sup> have well pointed out, Pope's old maxim holds for digitalis: "The proper study of mankind is man." It is evident that various digitalis bodies may be compared only by using the same test objects, and Gold insists that all digitalis should be standardized on man—in one sense this is true, but for practical purposes, it is evident from the modern work that in any *one* substance, relative potencies of different preparations may be determined with sufficient accuracy by the current methods of bioassay.<sup>3</sup> However, if one wishes to compare the potency of Lanatoside C, for example, with ouabain, they must be compared on the same test object,<sup>4</sup> and if they are to be compared on man, man is the proper test object. On the other hand, if one is using various preparations of Lanatoside C in the treatment of heart disease, a guide to the relative potency of various samples is afforded by bioassay on animals. Variations in absorption have also been studied.<sup>5</sup> Reference should also be made to the accurate observations of the Cornell group concerning the effects of digitalis on heart rate and efficiency.<sup>6</sup>

In the field of morphine action, progress is developing. Slaughter, Parsons and Munal's<sup>7</sup> emphasis on the cholinergic actions of morphine has led to fruitful explanations of a number of phenomena observed in morphine addiction and therapeutic use. Although their suggestion that

the use of prostigmine enhances the pain-relieving qualities of morphine has not met with universal confirmation, the experimental background is sufficiently clear to make persistence in developing this idea a worthwhile undertaking. Van Duzen, Slaughter and Winter<sup>8</sup> have recently studied the effects of Trasentin, a new synthetic atropinelike drug, and found it capable of counteracting the cholinergic actions of morphine. This recently introduced chemical has been studied in animals, and although it is different in many respects from atropine in its action and bears some resemblance to the action of papaverine, it appears to be worth further clinical trial—especially to relax bladder spasm.<sup>9</sup>

Caffeine and other diuretics have continued to share in pharmacologic interest. Too little work has been done with these substances by the modern methods of studying kidney function developed by Smith and his associates.<sup>10</sup> Evidence for the extrarenal action of caffeine was believed by Vollmer,<sup>11,12</sup> to be indicated by the fact that, in the rat, the output of chloride and potassium was increased by smaller doses than those required to increase the output of sodium. There is, likewise, some indication of extrarenal factors in the experiments of Swigert and Fitz<sup>13</sup> on the diuresis produced by mersalyl. Studies by Bodo and Bloch<sup>14</sup> on the effect of hypnotics and anesthetics on the diuresis of dogs with diabetes insipidus suggest some interesting possibilities in that striking differences in the diuresis-inhibiting effects of these drugs appeared evident. Some hypnotics failed to produce this inhibition, whereas others exhibited this property to a high degree. Additional work on caffeine is contributed by Barmack.<sup>15</sup> He points out that the boredom inseparable from repeated psychologic testing has a hypnotic quality, and he makes the ingenious suggestion that the apparent favorable effect of caffeine on psychologic performance may be due to its antihypnotic effect. Wolff and his co-workers<sup>16</sup> found caffeine to have no pain-threshold elevating power. The psychologic effect of mixtures of drugs to relieve pain seemed to have some weight in the results obtained by these workers. Unpublished evidence<sup>17</sup> indicates that caffeine counteracts the effect of certain analgesic drugs on peripheral pain thresholds and measurably lowers these thresholds. In this connection, it has been aptly pointed out that various alcoholic beverages are effective in proportion to their alcoholic content.<sup>18</sup> It should not be forgotten that alcohol is an effective analgesic agent.

Wolff and his co-workers<sup>19</sup> have also made measurements on the relative efficiency of morphine and certain related compounds in raising

the thermal pain threshold of the forehead. In general, Dilaudid was ten times as efficient as morphine, and morphine was two or three times as effective as codeine. Twenty milligrams of Pantopon was the equivalent of only 8 mg of morphine in these experiments, although previous experiments suggested that Pantopon is nearly as effective as the morphine it contains (that is, two thirds). Apparently, these workers found some antagonism between these opiates and epinephrine, which is to be expected if Slaughter's contention, that the pain-relieving action of morphine is also cholinergic, is correct.

Experiments on local anesthesia continue in the search for new and better agents, but occasional work dealing with clinical applications appears. The effects of epinephrine added to procaine and cocaine are well known. Small quantities are without effect, whereas concentrations greater than 1:50,000 markedly increase toxicity. Ephedrine in small doses diminishes the toxicity of cocaine, and in larger quantities increases it, but exerts no effect on the toxicity of procaine.<sup>20</sup> In a careful histologic study, Salm<sup>21</sup> showed that quinine salts in 1 per cent solution produce actual degeneration of nerve fibers. Although slight degeneration of a very few fibers was demonstrable after injections of physiologic saline solution into nerve fibers, the effect was in no way comparable with the destruction produced by the same quantity of quinine or quinine and urea hydrochloride. The effects of the saline solution are probably due solely to local pressure. It is evident that such effects argue strongly against the use of quinine and urea hydrochloride as a local anesthetic.

The effect of drugs on the action of hormones and vitamins is certain to be a subject of vital interest as time goes on, as demonstrated by the work of Samuels et al.<sup>22</sup> Salicylates increased strikingly the excretion of ascorbic acid. This increased excretion continued as long as the drugs were given. Caffeine and cinchophen produced a similar but much smaller increase in excretion. Single doses of salicylates produced a sharp rise followed by a compensatory fall. The practical implications are obvious.

Many more interesting "leads" appear to have been uncovered during the year, but at the moment, these are of theoretical rather than of practical interest. As their therapeutic implications develop, they will become appropriate topics in future reviews.

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

### CASE 27281

#### PRESENTATION OF CASE

A fifty-two-year-old single librarian entered the hospital for study.

The patient stated that she had always been very nervous, but had had no specific complaints until six months before admission, when she developed anorexia and a feeling of abdominal distention sometimes associated with constipation. These symptoms were relieved by exercise, but the period was marked by the appearance of exertional dyspnea and palpitation. Primarily for the latter symptoms, the patient consulted her physician, who prescribed iron, with some benefit. She carried on until nine days before entry, when the above symptoms became exaggerated and feverishness developed. Two days later, she apparently caught cold, with nasal obstruction and cough with small amounts of phlegm, which came from the nasopharynx. Three days before admission, she again consulted her physician because of dyspnea, which had become the most troublesome of her symptoms.

For the preceding two years the patient had noticed hot flashes, with a scanty menstrual flow, occurring about every eight weeks. From time to time during the previous year she had suffered from pruritus of the vulva and anus. All these symptoms had been controlled by osteopathy.

The patient's father had died at sixty-five of heart disease, her mother at sixty of cancer of the bladder. She had suffered from the usual childhood diseases, diphtheria and psoriasis.

On examination, the patient was well developed, well nourished and moderately short of breath. There was slight distention of the neck veins. Examination of the fundi showed thickening and tortuosity of the arteries, with arteriovenous nicking. The heart was enlarged to the right and left, and the sounds were forceful and regular, without murmurs. The aortic second sound was greater than the pulmonic; the blood pressure was 180 systolic, 125 diastolic. There were dullness to percussion and rales at the right lung base. In the abdomen there was a slight suggestion of shifting dullness, but no fluid wave. On pelvic examination, the hymen was found to be intact; by rectum, an irregular, slightly tender mass the

size of a grapefruit was found to be jammed but not impacted in the pelvis. An area anteriorly was unusually tender.

The temperature was 101°F., the pulse 140, and the respirations 24.

The urine showed a + test for albumin. The blood showed a red-cell count of 5,190,000 with a hemoglobin of 15.3 gm. (photoelectric-cell technique), and a white-cell count of 15,000 with 76 per cent polymorphonuclears. The nonprotein nitrogen of the blood serum was 15 mg. per 100 cc., the sedimentation rate 25 mm. in one hour. A blood culture and a Hinton reaction were negative.

An x-ray film of the chest showed the heart shadow to be grossly increased in size. The enlargement affected all chambers, but was most marked in the region of the left ventricle. Fluoroscopically, the pulsations of the heart were extremely weak, but the shape did not suggest pericardial effusion. The aorta was somewhat tortuous, but not dilated. The right costophrenic angle was obliterated by a small quantity of fluid; the lung fields were clear.

An electrocardiogram showed partial heart block, with a PR interval of 0.32 second and an occasional dropped beat. The ventricular rate was 125, and there was low voltage of all complexes in Leads 1, 2 and 3.  $T_1$ ,  $T_2$  and  $T_3$  were low or slightly diphasic;  $T_4$  was rather low.

The patient was given digitalis, and showed considerable subjective and objective improvement for a week or more. Two weeks after admission, an electrocardiogram showed normal rhythm with delayed auriculoventricular conduction, a rate of 95 and a PR interval of 0.25 second. There were low-voltage QRS complexes and low T waves, with an almost flat  $T_1$ ;  $ST_2$  and  $ST_3$  were depressed. The white-cell count was 15,000, the sedimentation rate 33 mm. in one hour. An x-ray film of the chest showed an increase in the amount of fluid in the right pleural cavity since the last observation, the fluid extending along the axillary line and in the interlobar fissure. The heart shadow was grossly increased in size, and the pulsations were barely visible. A few days later, the white-cell count was 18,200. An electrocardiogram showed a rate of 120 and delayed auriculoventricular conduction, with a PR interval of 0.23 to 0.24 second; there were low voltage, low  $T_1$  and slight sagging of  $ST_2$  and  $ST_3$ . On the twenty-second hospital day, the patient got out of bed to be weighed, and experienced sudden palpitation and dyspnea without pain. On examination she was orthopneic and cyanotic; the pulse was 88 and rather irregular. The heart

sounds were of poor quality, and there was fluid at the right lung base, with rales at both bases posteriorly.

Death occurred the following day.

#### DIFFERENTIAL DIAGNOSIS

DR PAUL D. WHITE: "Examination of the fundi showed thickening and tortuosity of the arteries, with arteriovenous nicking." Here are indications of changes of the fundi due to hypertension, and later the story suggests heart involvement that may have been secondary to hypertension. Are there any more blood pressure readings?

DR TRACY B. MALLORY: None are recorded. Dr. Fitzhugh, do you have further information?

DR GREENE FITZHUGH: The patient's blood pressure was normal when I saw her in my office about six months before entry to the hospital. The heart examination was essentially negative, and a rectal examination at that time showed no pelvic mass such as was found at the time of entry to the hospital. The patient came in because of pruritus. She did not return, and was seen by an osteopath until three days before entry.

DR WHITE: There is no statement about the liver. Was it felt?

DR MALLORY: One examiner thought he perhaps felt the liver down two fingerbreadths.

DR WHITE: There was evidently no appreciable liver enlargement.

There is some question whether the mass felt by rectum was responsible for the constipation and the difficulties at the beginning of the history, that is, the abdominal distention, anorexia and constipation. What was this mass—tumor or abscess; if tumor, ovarian or uterine, benign or malignant? It hardly seems likely that it was an abscess, and we shall return to the question of neoplasm later.

Weak cardiac pulsations on fluoroscopic examination are most often due to weak action of a large heart, but they may, of course, be caused by pericardial effusion or constriction.

The question comes up whether the pleural fluid was congestive or exudative, and whether there was anything else there, such as a lung infarct. For the lung hilar shadows, may we see the x-ray films? If the heart is very large, it may hide some of the hilar shadows, a fact about which we should like very much to know.

DR JAMES R. LINGLEY: The heart shadow is moderately increased in size, and there is a small quantity of fluid at the right lung base posteriorly in the costophrenic angle. The lungs are otherwise clear. I fluoroscoped the patient myself and was very much struck by the absence of cardiac

pulsations. It seemed more than one would expect with heart failure alone. Yet the shape of the heart did not suggest effusion. Furthermore, the clinicians at the time told me that the sounds were of good quality. That seemed quite unusual to me. The shape of the heart is not abnormal, but there is generalized enlargement. This later film shows increase in the amount of pleural fluid at the right base.

DR WHITE: Is there anything besides fluid?

DR LINGLEY: That is all I can make out. The fluid is extending into the interlobar septum at this point, but so far as I can see, the lungs are clear.

DR WHITE: There is fair evidence that the patient had hypertensive disease, based on examination of the fundi and on the enlargement of the heart. Certainly there was congestive failure.

The heart block is intriguing but not diagnostic. It hardly seems likely that digitalis was responsible, which leaves the following possibilities in the order named: coronary disease, complicating the hypertensive heart disease but without anginal pain; severe rheumatic myocardial lesions, which can occur in persons as old as this; and, as extreme rarities, neoplastic invasion of the heart, marked toxemia and, as in one or two cases we have encountered here, pulmonary embolism.

The febrile course, at least for a month, may be explained in a variety of ways, but not by congestive heart failure. Pulmonary infection and pulmonary infarction are the two best bets. Either one might explain the increase in dyspnea and death, but I think pulmonary infarction is more likely. It would readily explain the sudden episode the day before the patient died. Moreover, she had fever before she caught cold, according to the early history of the present illness. Rheumatic pancarditis, accounting for the heart block and fever, is another important possibility to be considered seriously, but the absence of antecedent rheumatic infection or heart disease is against it. The possibility, however, of a combination of rheumatic infection and pulmonary infection or infarction must be considered. Necrosis from extensive neoplastic disease, with thoracic metastases, is another but more remote possibility as a cause of the fever.

Finally, the pelvic tumor is of interest and perhaps of importance. I was inclined to pass it over on first reading. On second reading it occurred to me that it might explain everything, serving as a primary source of metastatic malignancy in the chest involving the lungs and pleura and even the pericardium, and the heart to explain

the heart block. I have never seen neoplastic heart block, but such cases are on record, although they are exceedingly rare. Then, on further reflection I decided that the pelvic tumor was very likely a red herring.

There is no statement in the record as to whether the mass was hard; it simply mentions an irregular tender mass the size of a grapefruit.

DR. FITZHUGH: It was moderately hard. The gynecologist thought it was a fibroid that had been overlooked at the previous examination.

DR. WHITE: I do not believe it was necessarily responsible for the final illness, unless the tender spot consisted of thrombosed veins that gave rise to the pulmonary embolism. However, Dr. Meigs,\* in his monograph on pelvic tumors, records one type of ovarian tumor, the Krukenberg tumor, that usually originates in the stomach and metastasizes to the ovaries and other parts of the body—the peritoneum, the lungs and even the heart. That may have happened here, but I cannot make a diagnosis on the data we have.

I should favor, in conclusion, the diagnoses of hypertensive heart disease and of congestive failure, complicated by recurrent pulmonary embolism, which finally caused death, arising quite likely from a pelvic thrombosis that complicated a fibroid tumor of the uterus or an ovarian tumor. I should not be greatly surprised, however, to learn of such a relatively rare condition as a Krukenberg tumor or another ovarian malignant tumor, with pericardial and myocardial metastases, or even of rheumatic pancarditis complicating the hypertensive state.

DR. J. H. MEANS: I was intrigued with a certain combination of evidence. The patient had a heart that was enlarged in all four chambers. By fluoroscopy the pulsations were noteworthy weak, and the electrocardiogram showed low voltage, with T waves in some leads that might interest one in a diagnosis of myxedema. However, she had a tachycardia, which would not be consistent with that unless Dr. Fitzhugh had been treating her with thyroid.

DR. FITZHUGH: No. She did not look myxedematous, and her basal metabolic rate was close to normal.

DR. MEANS: Does the condition suggest any sort of beriberi type of heart?

DR. WHITE: Beriberi might be mentioned as a possible background, although it could not explain the final illness; but I should not consider it seriously.

DR. HOWARD B. SPRAGUE: Do you think she could have had multiple myocardial infarcts?

DR. WHITE: In spite of the total absence of pain? One can have painless myocardial infarction, of course. Do you mean that the final episode might have indicated another myocardial infarct?

DR. SPRAGUE: Possibly.

DR. WHITE: I think that in view of the heart block we should diagnose some coronary disease complicating the hypertension, although we have seen heart block in other conditions, such as rheumatic infection and even pulmonary embolism. I do not believe that the heart block is specific enough to help in the diagnosis of coronary disease. With the absence of pain or of characteristic changes in the electrocardiogram I should not want to diagnose multiple myocardial infarction.

DR. FRANCIS R. DIEUAIDE: Is not the variation in the PR interval against any such possibility as a tumor involving the heart?

DR. WHITE: I do not know. There are so few cases on record that I cannot answer your question.

DR. DIEUAIDE: Unless you interfered with the delay by medication, you would not expect it to come down.

DR. WHITE: There is a great deal of variation in PR intervals in heart disease without much obvious change otherwise. But there may also be a change toward improvement when a heart rate drops, the PR interval decreasing. This may be due to an improved local coronary circulation to the bundle of His and its branches. There are too many factors controlling the PR interval to permit easy interpretation of its changes. The variations here, for example, do not rule out, I believe, metastatic myocardial neoplasm.

#### CLINICAL DIAGNOSES

Arteriosclerotic heart disease.

Pulmonary infarction?

Coronary occlusion?

#### DR. WHITE'S DIAGNOSES

Hypertensive, coronary heart disease, with congestive failure and partial auriculoventricular block.

Pulmonary infarction secondary to phlebitis caused by pelvic tumor.

Ovarian malignant tumor (perhaps the Krukenberg type), with metastases to lungs and pleura, to pericardium (with constriction) and to heart (to produce heart block)?

\*Meigs, J. V. *Tumors of the Female Pelvic Organs*. New York. The Macmillan Company, 1934. P. 213.

Rheumatic pancarditis (with pericardial and myocardial involvement), complicating hypertensive disease?

#### ANATOMICAL DIAGNOSES

Reticulum-cell sarcoma, involving multiple lymph nodes, heart, left ovary and peritoneum.

Pulmonary infarct.

Thrombus of right ventricle.

Fibrinous peritonitis, acute.

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: There was a large ovarian tumor, which was thought on gross examination to be an ovarian carcinoma, and there were numerous implants all over the peritoneum. The retroperitoneal nodes, however, were markedly increased in size, which is rather unusual with ovarian carcinoma. As one progressed upward, it became obvious that the tracheobronchial nodes were also large, and that a large tumor continuous with them had invaded the pericardium. Moreover, a large nodule of tumor was found in the heart itself, which extended a considerable distance into the myocardium, particularly in the region of the interventricular septum. The coronary arteries were not significantly narrowed, and there was no evidence of rheumatic infection, so that I believe we are safe in assuming that the heart block was due to the neoplasm. When microscopic examination was made, it was at once evident that this was not carcinoma but a form of lymphoma, which we classified as reticulum-cell sarcoma.

DR. WHITE: Was it metastatic from the ovary?

DR. MALLORY: To the ovary, I assume. It was presumably primary somewhere in the lymphatic system—where, I could not of course say, since the involvement was so general. There was an infarct of fair size in the lung, which had been present for a considerable period, perhaps a week or two. There was no final pulmonary embolus. The precipitate course of the last twenty-four hours was probably due to a terminal acute peritonitis.

#### CASE 27282

##### PRESENTATION OF CASE

A six-year-old boy entered the hospital complaining of pain in the right flank.

The patient felt perfectly well until four weeks before entry, when he began to have attacks of moderately severe, intermittent, nonradiating pain in the right flank. These attacks lasted about fifteen minutes and at first appeared in the late after-

noon, but thereafter in the early hours of the morning, at which time he would be awakened from a sound sleep. Furthermore, they occurred about twice a night and were accompanied by a desire to urinate. The mother believed that the child was urinating more than usual during the day. There had been no other urinary symptoms, nor change in color of the urine, fever, chills or gastrointestinal symptoms.

The child's birth and development had been normal. He had had measles, chicken pox and whooping cough.

On examination, the patient was well developed and well nourished and in no distress. The heart and lungs were normal; the blood pressure was 90 systolic, 60 diastolic. In the abdomen, there was questionable deep tenderness in the right upper quadrant. The urethral orifice was slightly redened.

The temperature was 99.8°F., the pulse 88, and the respirations 20.

The urine, voided with a normal stream, was cloudy, with a specific gravity of 1.012 and a pH of 5.5. It showed a ++ test for albumin, and the sediment was loaded with white blood cells. Three cultures yielded respectively no growth, *Staphylococcus albus*, and colon bacilli and non-hemolytic streptococci. The blood showed a red-cell count of 3,910,000 with a hemoglobin of 16.5 gm. (photoelectric-cell technic), and a white-cell count of 15,600 with 75 per cent polymorphonuclears. The nonprotein nitrogen of the blood serum was 28 mg., the phosphorus 5.0 mg. and the sugar 77 mg. per 100 cc. A phenolsulfonphthalein test showed 20 per cent excretion of the dye in the first fifteen minutes, and another 10 per cent in half an hour. A repeat test gave 55 per cent excretion in half an hour. The stools were normal. A tuberculin test was negative in a dilution of 1:1000.

An intravenous pyelogram and flat film of the abdomen showed incomplete fusion of the neural arch of the fifth lumbar vertebra, and the left kidney was much larger than the right. The dye was excreted promptly and incompletely demonstrated a normal-sized kidney pelvis on the right and a slightly dilated pelvis on the left. The calyces appeared normal.

Chemotherapy was instituted, and the urine cleared within four days, the white-cell count dropping to 7900; the temperature still spiked to 100°F. each day.

One month after admission, a cystoscopic examination was performed. The bladder appeared normal except for a slightly puckered and retracted right ureteral orifice. Both ureters were

catheterized easily, and a clear, equal flow came from each. One cubic centimeter of phenolsulfonephthalein was given intravenously, and the dye appeared from the left kidney in strong concentration within seven minutes. Ten minutes after injection, slightly dye-tinged urine appeared from the right kidney. A retrograde pyelogram showed a normal kidney pelvis on the left side and a markedly dilated kidney pelvis, with dilated calyces, on the right.

An operation was performed three days later.

#### DIFFERENTIAL DIAGNOSIS

DR. FLETCHER H. COLBY: The history and findings of this case suggest an infection of the urinary tract, and the field becomes narrowed down, I believe, to the right kidney. No intra-abdominal lesion, I think, need be looked for, although we must bear in mind that inflammatory lesions, particularly appendiceal abscesses, may give urinary symptoms, pus in the urine and a very well-developed degree of hydronephrosis from the pressure of the inflammatory mass in the abdomen. Here, however, there is no evidence of localization of symptoms in the abdomen and no evidence of peritoneal irritation, so that I think that any abdominal lesion can be ruled out.

Tuberculosis, I believe, can be eliminated because of the negative tuberculin test. At Lakeville State Sanatorium we have never had a patient with renal tuberculosis who has had a negative tuberculin test. In children, one naturally thinks of some congenital anomaly as a background of trouble. Could this child have had an anomaly of renal blood supply with some obstruction to the ureter, or such a thing as congenital narrowing at the ureterovesicular junction with infection? The absence of the neural arch of the fifth lumbar vertebra is one of the commoner anomalies, and I do not believe it is of any particular significance, but anomalies frequently run in pairs. The lower urinary tract seems to be well ruled out as a cause of trouble from such things as a congenital valve of the posterior urethra, because of the very clear statement that the child voided with a normal stream. So that attention is again focused on the right kidney. A right-sided pyelonephritis certainly seems to be the most obvious diagnosis.

There are two significant features in this protocol. The first are the facts that chemotherapy was instituted, and that within four days the urine became clear but the fever persisted. In other words, this child was not well. We know that collections of pus can rarely be successfully treated by chemotherapy and usually require surgical drainage, so that one cannot help thinking with

this sequence of events — the clearing of the urine and the persistence of the fever — that there was a collection of pus, either inside or outside the kidney. The second significant feature was the absence of any evidence of obstruction to the right kidney when this boy first came to the hospital, and one month later, the obvious development of right-sided renal obstruction.

This intravenous pyelogram was apparently taken soon after the child came into the hospital. Renal function was certainly adequate, but the right kidney did not excrete the dye nearly so well as the left. The left kidney outline looks large, but the right one is not at all well seen, and it would be unfair to compare their outlines on this film. The psoas muscle shows up well on the left, not on the right. The x-ray films taken one month later, at cystoscopic examination, show a fairly well-developed degree of dilatation of the right kidney pelvis and the calyces, whereas the left kidney looks very normal. Its outline is clearly visible. I cannot see the outline of the right kidney. Infection within the kidney itself, such as cortical abscess, would account very well for this picture, with the exception of this development of partial obstruction. Infection in the kidney will cause some degree of dilatation in the pelves and calyces, it is true, but it seems to me that something developed in this one month's stay in the hospital to cause obstruction to the right kidney; the most likely thing appears to be a collection of pus outside the kidney. The most reasonable sequence of events in this case seems to be a cortical infection of the kidney, with the later development of a perinephritic abscess.

DR. WILLIAM B. BREED: The obstruction developed with the decrease in renal function on the left. How do you account for that?

DR. COLBY: I think it was because of the presence of an inflammatory mass outside the kidney causing obstruction.

DR. BREED: Pressing on the ureter on the outside?

DR. COLBY: Yes.

#### CLINICAL DIAGNOSES

Pyelitis.

Hydronephrosis.

#### DR. COLBY'S DIAGNOSES

Chronic pyelonephritis.

Perirenal abscess.

#### ANATOMICAL DIAGNOSES

Double kidney.

Chronic pyelonephritis.

Hydronephrosis.

## PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: Dr. Smith, will you give us your preoperative diagnosis and describe your findings?

DR. GEORGE G. SMITH: Our diagnosis was hydronephrosis. I shall read the operative note.

Through a right oblique kidney incision, the kidney was easily freed and delivered and proved to be a double kidney, the upper half of which was plump and smooth, about 6 cm. in length, and drained by a normal appearing ureter. The lower half was drained by a large hydronephrotic pelvis and thickened and dilated ureter. The cortex was almost entirely destroyed, and the line of demarcation between the two halves of the kidney was very clear. Both ureters were followed down to the brim of the pelvis, at which point they were still separate. The ureter from the lower half was clamped cut and tied. The arteries supplying blood to the lower half, which consisted of a group of small vessels on each aspect of the kidney, were tied and divided. The lower half of the kidney was then separated from the upper half through the avascular line. The area thus made in the lower pole of the upper half was closed by two mattress sutures and a few superficial ones. Gerota's fascia below the kidney was sutured to the erector spinae muscle in two places. A rubber drain was left posterior to the kidney. The wound was closed in layers.

DR. MALLORY: I think it is safe to assume that there must have been a stricture of one of the two ureters on the right side at the point where it passed into the bladder, although the exploration was not carried far enough actually to demonstrate it.

DR. SMITH: On looking over the evidence afterward, I thought we might have made the correct diagnosis preoperatively if we had compared the films more carefully. This intravenous pyelogram

shows the ureter coming up here to a small pelvis close to the spine. The ureteropelvic junction, as I demonstrated it with the retrograde pyelogram, is 5 cm. lower and more lateral. I never compared these two films; if I had, I think I should have noticed the difference in the course of the ureter, as shown by the intravenous pyelogram and by the retrograde method.

DR. MALLORY: In other words, it was not the same ureter that you saw on the two occasions?

DR. SMITH: No.

DR. COLBY: Why did the dilatation increase?

DR. SMITH: I do not know that it did. There was no excretion on intravenous pyelogram from the lower pole of the kidney, and that was the thing that should have given us a diagnosis.

I might add that if I had done a phenolsulfonephthalein test with a catheter up the ureter and if I had obtained urine from the bladder at the time, as I should have done, I should have obtained the phenolsulfonephthalein that was excreted by the sound, upper half of the kidney. That would have been a confirmatory piece of evidence, but I should probably have attributed it to leakage from one ureter or the other.

DR. MALLORY: Do you think it probable that there was only one mouth to this double ureter in the bladder, or a second mouth that you did not observe?

DR. SMITH: It is possible that there were two, but I am rather inclined to think that there was only one, a Y-shaped ureter.

DR. MALLORY: As I have seen them, there has usually been only one mouth.

## MENTAL-HYGIENE CLINICS

ALTHOUGH there is little statistical evidence that mental disease is increasing throughout the world, except for such mental casualties as may be precipitated by the present war, its ratio in proportion to other disease at least remains constant. This means that mental disorders continue to constitute a most serious public-health problem. The fatalistic or pessimistic attitude is that some persons are destined to become insane because of their particular heredity or constitution and that, when this happens, they have to be cared for indefinitely in mental institutions or until, *Deo volente*, they are well again.

The average physician seems to be much less interested in the treatment of mental disorders than he is in advances in the therapy of other diseases. The reason for this may be that the

average physician believes there is so little to be done specifically for the mentally ill patient. The answer to this point of view might well be, like Shaw's defense of Christianity, What there is to be done has not been tried.

As indicated in an article in the July 3 issue of the *Journal*, the tendency to lock the door after the horse is gone—that is, to appropriate larger and larger sums for the custodial care of the insane, or for treatment after the disease is fully developed—is not in keeping with the obviously sounder concept of prophylaxis, which is today, almost as a matter of course, part of the treatment of physical disease.

Scientific interest in preventive measures in dealing with mental disorders arose as never before at the beginning of the present century. The advent of Freud and, in 1909, the establishment of the National Committee for Mental Hygiene introduced a feeling of hopefulness, which has persisted. At times and in certain quarters there has been too much enthusiasm in regard to prevention and cure, but on the whole, the shaking and disturbing of the static, pessimistic, nothing-to-be-done attitude have been healthful.

The work of the committee resulted in the establishment of more and more child-guidance and mental-hygiene clinics in this country through the years from 1913 to 1931. Since 1931, although some clinics have been closed, others have been opened, and their value seems to be proved by the fact that almost all have more demands on their resources than they can satisfy.

Unquestionably there are some persons who are destined to become psychotic because of a deep-seated structural or personality defect or predisposition. However, unless one is completely fatalistic about human destiny, believing that education and environmental influences play no part whatever in the paths we take, there can be no doubt that nurture, as well as Nature, has something to do with what happens to us. And it is human to believe in the possibility of change.

In treating any disease, it is not possible to know the proportional value of all the factors that may act in effecting improvement or cure. It would not

be reasonable to assume, however, that factors which have been present and used again and again in successful treatment have no bearing on the cure or amelioration. When children who present difficult behavior problems in unwholesome home environments become tractable and co-operative in more healthful foster homes, it seems fair to assume that the change in environment had some relation to the alteration in behavior.

Ross\* presents statistics that weigh in favor of the value of psychotherapy. Whether or not patients with emotional or mental difficulties are completely cured for all time is comparatively unimportant. No person can be guaranteed against all forms of disease throughout his life span, but countless patients attest to the help they have received from psychotherapy in leading more contented and useful lives. The public and the psychiatrists and mental hygienists themselves would have to be dupes, indeed, to continue the support of psychiatric and mental hygiene clinics for more than a quarter of a century in the absence of fruitful results. Allowing for the gullibility of those who suffer and need help and for the human frailty that permits any system to continue so long as it provides financial gain for its advocates, the evidence is that psychotherapy works, on its own merits.

The clinics cannot be maintained and become increasingly effective through the sole interest of those primarily concerned professionally. Physicians in general, and through them, the public, in families, schools and courts, must recognize the preventive and therapeutic aid that is available and that, through their understanding and efforts, can be increased.

## DRUG SAMPLES

UNDER "Current Comment" in the January 25 issue of the *Journal of the American Medical Association* appeared an item entitled "Sample Racketeers." This called attention to an abuse which seems so petty as hardly to merit editorial

comment. Subsequent information, however, leads one to believe that it is more widespread than would be thought. Indeed, New York City has added to its sanitary code a regulation specifically forbidding the marketing of packages conspicuously labeled as samples. Little or no evidence of this practice in Massachusetts is apparent. However, if such an abuse can be shown to exist, it is proper for the medical profession to support such legislation if it is presented to the General Court.

Lately, requests have been made that these samples be collected by physicians and be included in shipments for British relief. This movement should be distinctly discouraged, since almost all pharmaceutical manufacturers have donated generous supplies of needed products, and since the scheme would result in a collection of heterogeneous material—some of it of little or no value—that should not be used indiscriminately.

Another facet of this situation suggests a question of the desirability of using the widespread distribution of pharmaceutical samples as a method of advertising. Although, of course, this is primarily a commercial problem, it is apparent that under the new federal Food, Drug and Cosmetic Act there seems to be little logical reason for manufacturing pharmacists to distribute samples through the mail urging the recipient to "try this." The new act makes it mandatory that any preparation shall have thorough clinical trial prior to being put on the market. If such a preparation has complied with the spirit of this act, it should be unnecessary for the individual physician to be annoyed with an accumulation of samples, most of which find their way into the wastebasket or remain as "dust catchers" to the annoyance of the wife, secretary or charwoman who dusts the office.

Elimination of this method of advertising would save time, money, postage and labor, and the price of the finished product to the patient could thus be reduced. Instead of the indiscriminate distribution of samples, free distribution of medicines might be limited to the fulfillment of bona fide requests for substances to be used in investigative work.

## MEDICAL EPONYM

### HUNTINGTON'S CHOREA

George Huntington (1850-1916), of Pomeroy, Ohio, read an essay before the Meigs and Mason Academy of Medicine, Middleport, Ohio, on February 15, 1872, "On Chorea," which was published in the *Medical and Surgical Reporter* (26: 317-321, 1872).

And now I wish to draw your attention more particularly to a form of the disease which exists, so far as I know, almost exclusively on the east end of Long Island. . . . Chorea, as it is commonly known, . . . is of exceedingly rare occurrence there.

The hereditary chorea, as I shall call it, is confined to certain and fortunately a few families. . . . It is attended generally by all the symptoms of common chorea, only in an aggravated degree hardly ever manifesting itself until adult or middle life; and then coming on gradually but surely, increasing by degrees, and often occupying years in its development, until the hapless sufferer is but a quivering wreck of his former self.

Boston

### DEATH ASSOCIATED WITH SHOCK FOLLOWING A LOW-FORCEPS DELIVERY

A thirty-seven-year-old para II had received adequate prenatal care, having been seen routinely after the third month. Physical examination was entirely negative. The blood pressure was normal—124 systolic, 70 diastolic. The urine contained no albumin; there was no bleeding or other complication during pregnancy.

The patient entered the hospital in labor at term. After a normal labor of twelve hours and after the vertex had presented at the introitus for forty-five minutes, a low-forceps operation was performed. The baby was large, although the specific weight was not given. There was so much difficulty in delivering the shoulders that, even in the absence of hemorrhage, the cervix was inspected; no tear was noted. There was no unusual amount of bleeding. In spite of this, a rapid pulse, low blood pressure and clammy skin immediately developed, and the patient went into shock, from which she died ten hours later.

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section.

*Comment.* In the absence of post-partum hemorrhage, this death was attributed to shock. Whenever there is extreme difficulty in the birth of the shoulders, rupture of the uterus must be thought of. It is possible that, in spite of a cervix that did not appear to be torn, a tear in the lower segment of the uterus might have existed.

This patient was not transfused. This was an obvious oversight, because transfusion is of inestimable value in shock.

There was no autopsy, and if the report is an honest and intelligent one, shock must have been the cause of death, although rupture of the uterus cannot be ruled out.

## COMMITTEE ON STATE AND NATIONAL LEGISLATION

H. 115, which provided that physicians should register with their town clerks, was passed by the Committee on Ways and Means, with the recommendation "ought to pass." It was, however, referred to the next General Court by the House on June 26.

H. 114, the annual-registration bill, was reported favorably by the Committee on Public Health but was referred to the next General Court by the Committee on Ways and Means; this action was approved by the House on July 3.

Both these bills were opposed by the Society.

HENRY C. MARBLE, *Chairman*

## DEATHS

HOPKINS—FREDERICK E. HOPKINS, of Springfield, died July 1. He was in his eighty-fourth year.

Born in Richford, Vermont, he attended St. Johnsbury Academy and the University of Vermont, receiving his degree from New York University Medical College in 1884. He was formerly consulting laryngological surgeon at the Memorial Hospital, Brattleboro, Vermont, and was a former president of the New England Laryngological and Otological Society.

Dr. Hopkins was a fellow of the Massachusetts Medical Society and the American Medical Association, and held memberships in the American Laryngological, Rhinological and Otological Society and the American College of Surgeons.

His widow, a son, Dr. Frederick S. Hopkins, and six grandchildren survive him.

RYAN—DENNIS M. RYAN, M.D., of Ware, died June 14. He was in his eighty-second year.

He received his degree from the University of Vermont College of Medicine in 1884, and had practiced medicine in Ware for fifty-three years. He was formerly on the staff of the Mary Lane Hospital, Ware. Dr. Ryan was a member of the Massachusetts Medical Society, the American Medical Association and the Brookfield Medical Club.

His widow, three sons and ten grandchildren survive him.

## CARE OF THE SKIN \*

The care of the skin is a prime requisite of health. From infancy to old age it is subjected to various insults from our so-called civilized manner of living.

The infant's tender skin requires the utmost care. For its daily bath only a mild soap should be used, the skin thoroughly dried, and a bland oil applied, followed by dusting a borated talc on the folds of the skin. Final rinsing of diapers with boric acid solution offsets the alkalinity of the urine, and prevents diaper rash. Overheating of the nursery, overclothing and irregular or excessive feeding make infants fretful and irritate their skins. When a rash appears, a physician should be consulted immediately, for impetigo or eczema may be promptly relieved if treated at the onset.

At the school age, the communicable diseases appear. Daily examination of a child's scalp and skin will reveal any contagious disease, daily bath and change of clothing may prevent them. At adolescence, acne with its blackheads, oiliness and pimples makes its appearance and needs treatment. The concept that youth will outgrow this condition may result in its persistence, with resulting scarring and an inferiority complex that may last throughout adult life. The boy or girl at the high school age desires a clear skin, and treatment should begin as soon as the acne appears. Outdoor exercise, careful diet, regular hours and elimination, with suitable local medication will produce excellent results. Creams and massage should be avoided; the former increase the greasiness and the latter spreads the infection. Soap and water cannot be used too frequently at this age, except in those adolescents with dry or eczematous skins.

Adults should become skin-conscious at home, at work and at play. The skin offers protection against the onslaughts of the outside world, if abused it rebels with outbursts that may vary from a simple inflammation of the skin, or dermatitis, to cancer. Fatigue, emotional stress, overeating, overindulgence in alcoholic beverages and constipation register their effects on the skin. Most curable diseases can be prevented. An intact, soft, pliable skin protects against external irritants and micro-organisms, but dryness and the slightest break in its continuity may lead to eczema or infection. Injuries, irritants and unsuitable clothing should be avoided. The last should be lightweight, soft and seasonal. Washable garments should be worn next the skin, and new ones should always be washed to remove the sizing or backfill before wearing, for this sizing may damage the skin.

Concentrated soap mixtures should be thoroughly rinsed from clothing before drying. Too-powerful alkalis are harmful and are too frequently used by laundries. Care should be exercised in the choice of soap or soap powders. Medicated soaps are of no value and should be avoided, especially those containing mercury or resorcin. All dermatologists realize that soap and water are invaluable in the care of the skin, but the excessive use of soap and soap powders causes nearly 20 per cent of all the eruptions that appear on the hands. These are not trivial ones, but may last for months or years, are disabling, and often lead to serious infections. The best soaps contain very little free alkali, superfatted soaps such as shaving soaps are to be preferred. Careful drying of the skin is important. When prolonged or frequent exposure to soap and water is necessary, rubber gloves over cotton gloves should be worn and a soothing cream rubbed into the skin at the end of the day's work. Well

advised lotions often contain glycerin, which is drying and not so beneficial as vaseline, lanolin, or cold cream, used either singly or combined.

The majority of cosmetics are harmless, a few are beneficial. A soothing cream and a bland powder will protect the skin from the dry overheated air of rooms, and from the ravages of the wind, dust and sun. They must be removed with soap and water at the end of the day. In middle age, creams are useful and may prevent dryness and senile changes. Most claims are absurd—wrinkles cannot be eliminated, nor can the skin be nourished; these must be corrected from the inside, not the outside. Creams containing mercury, such as bleaches, should be avoided. The literature on all cosmetics should be carefully read for if cosmetics contain dangerous ingredients it will be noted on the labels or directions. Face powder should not contain orris root or heavy metals. Perfumes should never be applied to the skin before exposure to the sun, for this may lead to a disfiguring permanent discoloration. Hair dyes and rinses, which are really dyes, are dangerous and eventually cause distressing symptoms. Depilatories may be harmful, and deodorants should be used with care. Frequent permanent waving injures the hair, singeing of the hair is a senseless procedure. Lipstick and nail polishes contain sensitizers and may produce eruptions at areas other than the site of application—for example, about the eyes or on the neck.

Speaking of sensitizers recalls the word allergy, which means an altered reactivity, for example, a person reacts unfavorably to a substance that will not affect most people. I believe that everyone has his own pet allergy and that about 10 per cent have allergies or hyper-sensitivities that need medical attention. The substances that cause allergy are called allergens. They are innumerable and result in all types of eruptions—simple swelling of the skin, hives, sores in the mouth, discolorations, painful growths like pimples or boils, dermatitis, eczema and even death. Bromides and sleeping pills are the worst offenders. If a rash occurs while you are taking a medicine, even aspirin, stop taking it, for drugs are common allergens. If you apply an antiseptic to a cut and it becomes red, blistered and itchy, do not use it again, you are probably hypersensitive to it and should consult your physician and tell him what you applied. Allergy can be due to food, pollens, flowers, fungi, cosmetics, clothing, adhesive tape, industrial contacts and physical agents such as heat, cold and sunlight. A sensitivity may develop after years of contact. A woman may use a face powder or cream for years before it causes a dermatitis. People sensitized to nickel may react to the handling of any nickel-plated object, even safety pins. Everyone should learn to recognize the neighboring poisonous plants, especially poison ivy or oak and primrose. The latter should never be allowed in a house.

Painful feet are disabling, and proper care can prevent them. Careful selection of footwear and daily bathing with hot water and baking soda, followed by massage with linolin, will prevent the formation of painful calluses and plantar warts. Careful drying between toes and a borated dusting powder are good preventives of athlete's foot. Its causative factor is a mold or fungus, which is found lurking everywhere for the unsuspecting barefoot. Footwear should be worn at all times, on the beaches or in showers.

Any change in the skin demands prompt expert medical advice. An enlargement of an old mole or blemish or the persistence of a new one should suggest cancer and prompt attention. No one need die of cancer of the skin, it can be cured by early treatment.

\*A Green Lights to Health broadcast given through State WAAAB by Dr. John G. Downing on March 26, 1941 and sponsored by the Public Health Commission of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

## MISCELLANY

### NOTES

The Howe Research Medal, awarded by the Section of Ophthalmology of the American Medical Association, was given this year, for the first time since 1938, to Dr. Walter B. Lancaster, professor of ophthalmology and chief-of-staff, Clinical Division, Dartmouth Eye Institute. This medal is presented "to any person in any country whose researches in ophthalmology or any of the allied branches of surgery have proved to be of distinguished merit." Dr. Lancaster, formerly of Boston, assumed his new duties at Hanover last fall.

At the annual meeting of the American Neurological Association, Dr. Abraham Myerson, professor of neurology (emeritus), Tufts College Medical School, and clinical professor of psychiatry, Harvard Medical School, was elected second vice-president.

## CORRESPONDENCE

### "THE CLOSED-STAFF HOSPITAL"

*To the Editor:* I wish to protest as absolutely false the following statement in an editorial, "The Closed-Staff Hospital," in the June 5 issue of the *Journal*.

In particular they fail to recognize that any member of the medical profession, regardless of the school from which he graduated or the societies to which he belongs, who can demonstrate to fellow members in his community, and to the trustees of the hospital that serves his community, that he is technically equipped, adequately trained, ethical and desirous of keeping constantly up to date in his profession will have no difficulty in obtaining permission to practice in his local hospital, even though it is inspected and certified as meeting the minimum requirements of the American College of Surgeons.

It is general knowledge among physicians that there is definite and complete discrimination on the basis of school alone. For example, in 1937 one of the local hospitals voted to admit to practice in the hospital only graduates of accredited medical schools. How much of this comes from the headquarters at Chicago and how much is of local origin, I do not know. I feel that any discrimination in a competitive profession that gives a monopoly of hospital practice to certain individuals at the expense of other individuals in the same profession and often in the same society, is open to question. The White Cross seeking a monopoly in house and office as well as hospital practice is simply an extension of the same idea.

If membership on a hospital staff were decided by an impartial examination, there could be no feeling of discrimination as there is at present.

MILMAN PEASE, M.D.

Brookfield, Massachusetts

*To the Editor:* I have just read the editorial on closed hospital staffs in the June 5 issue of the *Journal*, and consider it well composed, but unfair in that it fails to mention the evils which rise from hospital oligarchy. Political and personal, rather than professional and ethical, qualifications inevitably influence the selection of staff men, and there arises an intolerable tyranny even over the selected physicians. Their willingness to "clean house" puts them at the mercy of laymen and physicians

more interested in profit or in power than in the practice of good medicine. The threat of exclusion has been used to coerce young doctors into performing suicidal "charity" services, or into guaranteeing the payment of their patients' hospital bills. Capable anesthetists and other specialists have been discouraged by encountering exclusiveness more shameful than that of the "closed shop."

Where county societies exist, active and representative judicial councils correct abuses of medical ethics. A hospital staff is far less likely to give impartial consideration to a physician's ethical and technical qualifications than is such a judicial council, responsible to the entire profession. What council can compel hospital trustees to manumit their medical slaves?

If general practice is to survive, and if medicine is to remain the progressive and personal profession of which we are proud, hospital facilities must remain at the disposal of the entire medical public, and neither religion nor influence nor servility may be the requisites for access to their use.

AUSTIN BLOCH, M.D.

1301 Hepburn Avenue  
Louisville, Kentucky

\* \* \*

In the editorial referred to in the above letters, eligibility was considered a matter to be decided, on the basis of proper professional qualifications, by the hospital rather than by any set rules laid down by another organization. Religion, influence or servility should not enter into the decision; but, if the qualifications stated in the sentence quoted in the first letter are met, the *Journal* is of the opinion that the graduate of a nonapproved medical school would, or at least ought to, have little — possibly "no" — difficulty in obtaining permission to practice in his local hospital. — Ed.

## ELECTROENCEPHALOGRAPHIC STUDIES OF TWINS

*To the Editor:* Under a grant from the Committee on Human Heredity of the National Research Council, we are making a study of the heredity of cortical dysrhythmia. We should appreciate the opportunity to make electroencephalographic records of identical twins of any age, normal or sick, although we should be especially glad to have subjects in whom one or both have a disorder of the central nervous system. The examination causes no discomfort, and the subjects used will be recompensed for time and travel. All who are interested should write or telephone me at the Neurological Unit, Boston City Hospital (KENmore 8600, Extension 654).

WILLIAM G. LENNOX, M.D.

Boston City Hospital  
Boston

## REPORT OF MEETING

### NEW ENGLAND ROENTGEN RAY SOCIETY

A regular meeting of the New England Roentgen Ray Society was held at the Boston Medical Library on April 18, with Dr. George W. Holmes presiding.

The first discussion was by Dr. Claude E. Welch, of the Massachusetts General Hospital, on "Gastric Ulcer and Its Relation to Carcinoma of the Stomach." Gastric ulcer was said to be rare, compared with duodenal ulcer and gastric carcinoma. A study was carried out to confirm a preconceived idea that the clinical and roentgenologic manifestations of gastric ulcer and cancer are similar in a high percentage of cases, that carcinoma resembling

ulcer is a favorable lesion, and that ulcers, therefore, should be treated surgically, especially by subtotal gastric resection. Two hundred and fifty-five cases were studied in which the mortality on medical treatment was 4 per cent, and on surgical management 10 per cent, with a combined figure of 7 per cent. In 39 cases in which the preoperative diagnosis was ulcer, the final diagnosis was cancer, and 17 cases originally classified as cancer were ultimately proved to be benign ulcer. Among the 69 resected cases in which the preoperative diagnosis was obtained from the surgeon, internist, roentgenologist and pathologist, there was a 43 per cent error, by one or more observers, in naming carcinoma benign ulcer. All four were wrong in 26 per cent of the cases. A more serious mistake was the finding of cancer in 17 per cent of posterior gastroenterostomy cases, and in 7 per cent of the medically treated cases, with the latter, 12 of the 13 cases finally reached surgical intervention only after having been followed for more than ten months.

It has been suggested that various criteria may aid in the differentiation of benign and malignant gastric lesions, but these have been evaluated and found wanting in many cases. The age of the patient is probably significant in that there is a high incidence of cancer in the group over fifty years, especially when signs and symptoms have been present for less than one year. Duration is of some value, for the possibility that cancer may cause symptoms for more than five years is unlikely. The site of the lesion is important, for those on the greater curvature are almost 100 per cent malignant and those in the prepyloric region 65 per cent cancerous, whereas ulcers of the anterior and posterior surfaces and of the pylorus are malignant in only 20 per cent and 10 per cent of cases respectively. In regard to the size, it is a fair statement that the percentage of carcinoma is high in large lesions, especially in those more than 2.5 cm in diameter. The amount of hydrochloric acid is significant only if there is none, for carcinoma associated with ulceration has essentially the same amount of acid as a benign ulcer. The rate of healing and the type of pain have been found particularly unreliable as criteria of differentiation.

Of all resected cancers of the stomach, the mortality was 25 per cent, and the five year curability 20 per cent. Of those originally diagnosed as benign ulcer, on the other hand, the mortality was only 10 per cent and the curability 40 per cent. The improved prognosis in the latter group is therefore apparent. The total mortality for all subtotal resections was 9 per cent, and for those previously unoperated on only 6 per cent, as compared with a mortality of 14 per cent in posterior gastroenterostomies. Furthermore the statistics for subtotal resection have been improving with experience, and this operation is strongly recommended because of its low mortality and certain diagnosis. Even in comparison with medical treatment, subtotal resection makes a creditable showing for adding the deaths from cancer (8 per cent) to the operative mortality (6 per cent) gives a total of 14 per cent whereas the medical deaths of 4 per cent when added to the deaths from cancer (13 per cent) amount to 17 per cent.

In conclusion, immediate surgery was advocated in lesions of short duration, especially when the patient is over fifty years of age when the lesion is more than 2.5 cm in size, if there is anacidity, if the site is on the greater curvature or in the prepyloric region, and if there is a chronic lesion on the lesser curvature. Medical management should be tried in acute ulcers, in young patients when the lesion is small, and when the site is in a low cancer incidence area. Such a lesion should heal in one

month and should be checked roentgenographically in another month.

The next presentation was an associated discussion, entitled "The Roentgenologic Similarity of Benign and Malignant Lesions," by Dr James R. Lingley, of the Massachusetts General Hospital. Mobility, size, tenderness, spasm, the presence or absence of rugae, and the location and type of ulcer may give clues when correlated, but no single criterion can ever be routinely relied on for differentiation. Improvement under a medical regimen is no certain indication of the benign character of the lesion, for an ulcerated malignant lesion will often give the same response. Numerous case reports were cited as evidence of the unreliability of any one or even several combinations of these various diagnostic points.

Dr Tracy B. Mallory, of the Massachusetts General Hospital, then discussed "Malignant Ulcers of the Stomach." The differentiation of malignant and benign gastric lesions is often impossible grossly, and exceedingly difficult even microscopically. Carcinoma in situ existing as long as seven years has been proved in the uterine cervix. This noninvasive stage of cancer differs from so-called precancerous lesions in its irreversible character, for the latter may often not progress to malignancy. Carcinoma in situ is autonomous only in its own habitat. Many such lesions have recently been demonstrated in prepyloric ulcers resected at the Massachusetts General Hospital. Photomicrographs demonstrated the differences between normal gastric mucosa, the intestinal metaplasia sometimes seen in normal adults, benign peptic ulcer, with its red fibrinoid layers at the site of active digestion, and ulcerated carcinoma, with its poor regimentation of nuclei and large and irregular mitoses. It was reiterated that ulcerated carcinoma of the stomach has all the characteristics of a benign ulcer. Cancer in situ cannot be determined grossly at operation much less roentgenographically or clinically, and there have been no recurrences in such cases subjected to subtotal resection at the Massachusetts General Hospital. Therefore, this should be the treatment of choice.

Dr Richard Schatzki, of the Massachusetts General Hospital, discussed "The Followup of Patients with Carcinoma of the Larynx." A study of such cases treated by roentgen rays at the Massachusetts General Hospital from 1934 to 1938, usually after being refused surgically, revealed that 11 of 33 patients were alive from three to seven years after treatment. Disappearance of the lesion usually occurs almost immediately, if at all, and recurrence after a year and a half is virtually unknown. The grade of malignancy seems inconsequential as a determinant of curability. Lateral films, as well as bronchoscopy, are employed to locate the site and extent of the lesion. Treatment should consist of large doses over a short period, with no repetition later. Doses of 3000 to 3600 r to each side of the neck, or 300 r per day, are delivered with occasional additional amounts if the immediate result is good and the skin reaction not too marked. Tracheotomy diminishes the chances of cure, and better treatment obviates the need for such a procedure.

Dr LeRoy A. Schall pointed out that cures as high as 80 per cent are obtained by surgical methods in lesions confined to the vocal cords, with a mortality of only 1 per cent and a short hospital stay. Subglottic cancers are not radiosensitive and should be treated surgically if Grade I and probably if Grade II, since a curability rate of 75 per cent is obtainable with laryngofissure. In the more extensive lesions in which laryngectomy was performed 74 per cent of patients are alive without disease. In conclusion it was advocated that the roentgenologist be

given an opportunity to improve these statistics by treating favorable cases.

The roentgenologic treatment of polycythemia vera was discussed by Dr. Laurence L. Robbins, of the Massachusetts General Hospital. Diagnosis is made by the finding of a persistently high erythrocyte count, splenomegaly, a normal oxygen saturation of the blood (in contrast to compensatory polycythémias) and marrow biopsy, if necessary to rule out leukemia. Sixteen patients with thrombophlebitis and bleeding were studied, and remissions up to five years were obtained in 13 cases. A series totaling 500 r is given at the rate of 50 r per day, alternating anterior and posterior portals and using a spray method. Treatment is stopped if the leukocyte count drops below 4000, but all the good responses occurred in cases in which this count was less than 6000. Improvement should appear in less than three months, and another course may be attempted cautiously if there is no response within that period.

The final paper was a discussion, "The Removal of Lipiodol from the Spinal Canal," by Dr. Aubrey O. Hampton, of the Massachusetts General Hospital. Surgical removal at operation has not been successful, whereas the proper suction technic has given good results in almost all cases. The patient is placed face down, with a pillow under the abdomen. An unbreakable needle is inserted between the third and fourth lumbar vertebral spines, since most ruptured intervertebral disks occur in the next space below and should be avoided. Removal is favored by an early carrying out of the procedure, which is now performed as soon as the spinogram has been taken and observed. The entire method requires only thirty to sixty minutes. Suction should be very gentle. Pain indicates improper position of the needle.

## BOOK REVIEWS

*Population: A problem for democracy.* By Gunnar Myrdal. 12°, cloth, 237 pp. Cambridge: Harvard University Press, 1940. \$2.00.

The medical profession helped to create the problem of population pressure, for scientific medicine and the public-health movement have saved lives. It therefore behooves the physician to interest himself in modern aspects of demographic problems.

Although population presses on food in China, India and some other parts of the world, in the United States and in western Europe, until the recent war at least, food pressed on population. Malthus was not wrong. He merely needs to be restated. Professor Myrdal, a distinguished Swedish economist, attempts to do this.

With a net reproduction index of around 0.75, the Swedish population is not reproducing itself. The same condition exists in many American cities. Probably the population of the United States, as a whole, is just about reproducing itself when allowance is made for the excess of women in the childbearing period. Soon we shall have a stationary population.

Will the fears engendered by that condition create many crackpot schemes for increasing population? Professor Myrdal thinks so. He wants Americans to be forewarned, to take thought now, to plan intelligently for the future. He analyzes Swedish conditions in the hope that American scholars may be able to give intelligent guidance in the future. He combines the clear thinking of the scientist and the statistician with a statesman's regard for the long-run welfare of the family and the state.

The author insists that the difficult problem of inducing the healthy and intelligent to reproduce in sufficient numbers must be met within the framework of democratic institutions and not by means of fascist, short-cut methods, intolerable to a free people. Even if more reproduction is needed, it must not be at the expense of the poor, ignorant and unhealthy.

There is no space to analyze in detail Professor Myrdal's economic and social program. Suffice it to say that it recommends, among other things, subsidies in kind (not money) for better housing and nutrition of children without a means test. Married women should be protected in their jobs when they try to combine maternity with a limited career. A more thorough child-welfare program is called for to reduce the burden of those who bear the brunt of the cost of childbearing. The Swedish program should be seriously studied to determine how far it can be adapted to this country before a stationary population is reached in about 1960.

*Compendium Physicac.* By Charles Morton. Compiled about 1680. Publications of The Colonial Society of Massachusetts. Collections: Vol. 33. 8°, cloth, 237 pp. Boston: The Colonial Society of Massachusetts, 1940. \$5.00.

Morton's *Compendium*, here printed for the first time, was circulated among Harvard College students in manuscript from 1687 to 1728 as the textbook in science. Morton wrote it in England about 1680 and brought it to this country in 1686. The book had an immediate effect, as noted in the Commencement theses of 1687. The manuscript has been carefully edited from a number of copies, and a preface on Morton's life has been supplied by Professor Samuel E. Morison of Harvard University. The publication of this volume is an important contribution to the history of science in America by the Colonial Society of Massachusetts. The book has been printed by the Merrymount Press in an impeccable format.

*Bellevue.* By Lorraine Maynard. In collaboration with Laurence Miscall, M.D. 8°, cloth, 280 pp. New York: Julian Messner, Incorporated, 1940. \$2.50.

A great metropolitan hospital is viewed, in newspaper slang, "through the eyes of a woman," with a collaborating doctor. This fast moving book, written for the public, gives what is described as a look "behind the scenes into the human drama of the world's most famous hospital." There is not much of medical interest in the book, and the public must wonder if this is really all that goes on as a routine in a big hospital. Some of the stories are good, but the whole style of the book is theatrical and Hollywoodish.

*A History of Medicine.* By Arturo Castiglioni, M.D. Translated from the Italian and edited by E. B. Krumbhaar, M.D., Ph.D. 8°, cloth, 1013 pp., with 443 illustrations. New York: Alfred A. Knopf, 1941. \$8.50.

This large, well-illustrated history of medicine, by the foremost Italian medical historian, has long been known to scholars in Italian and French editions. An English edition for American and British students, translated from the Italian by Dr. Krumbhaar, a distinguished American scholar, is now at hand.

The book covers the whole field of medicine and is particularly rich, as might be expected, in the glorious history of the Italian contributions to the subject. Much of American history, however, has been skillfully woven

into the text by the translator, and the book remains as a standard, complete text of great value. Not so factual as Garrison's *Introduction*, nor so widely documented as multivolume German surveys of the past, Castiglioni's book nevertheless finds a place in the literature of our time and will be extensively used, without replacing other books. For the average student or physician it can be soundly recommended. This book and Garrison's final edition will long be two cornerstones of a medical history library. Finely printed and illustrated, the book is a credit to American publishing.

*The 1940 Year Book of Pathology and Immunology*  
 Edited by Howard T. Kirsner, MD (pathology) and  
 Sanford B. Hooker, MD (immunology) 12°, cloth, 698  
 pp, with 113 illustrations Chicago: The Year Book  
 Publishers, Incorporated, 1940 \$3.00

This book should prove a welcome addition to the library of the pathologist and bacteriologist. Arranged in the now familiar "year book" form, it is divided into two sections: one on pathology and the other on immunology. The abstracts of important papers are well written and informative. On the whole the difficult problem of choosing papers for review has been well solved. The reprinting of over one hundred illustrations from the original papers adds definitely to the value of the volume. The authoritative scope of this year book would perhaps be enhanced by the inclusion in both sections of the book of more short reviews of the general type of the five selected in the section on pathology.

The book is well printed and of convenient size. The authors are to be congratulated on the success of their undertaking.

*Rôle de la constitution dans les maladies infectieuses des enfants*  
 By Hanna Hirsfeld 12°, paper, 152 pp, with  
 20 illustrations Paris: Masson et Cie, 1939 70c

Resistance to the specific infectious diseases varies markedly according to age, environment and, apparently, sundry other conditions. Racial immunities, relative at least, or, conversely, racial susceptibilities seem often enough conspicuous. Dr Hirsfeld believes, from the study of these together with the study of resistance in certain families and moreover, in plants and animals, that the factor of heredity is of very considerable weight. The transmission of resistance follows Mendelian laws, passing by way of a recessive gene. This is an interesting discussion, but in haphazard human breeding it seems to be of comparatively small practical importance.

*Heart Failure* By Arthur M. Fishberg, MD Second  
 edition thoroughly revised 8°, cloth, 829 pp, with 25  
 illustrations Philadelphia: Lea and Febiger, 1940 \$8.50

The first edition of this book appeared in 1937. In less than two years the entire edition was exhausted. The success of this volume is no accident, since the trend of modern medicine is toward a pathologicophysiology approach. The twentieth century physician is not so much concerned with "what happened," as with the "why" and "how." The contributions of the present era are more

expository than descriptive, the classic descriptions of disease being of the period that has passed.

Dr Fishberg has limited his subject to a minute field in medicine, and proceeds to expound all the processes involved. Yet a wide range of subjects is embraced: cardiac output, velocity of blood flow, arterial and venous pressure and pulse, and dyspnea, to mention only a few. It was once said that he who masters the subject of syphilis will know practically all medicine, for it simulates many diseases. The same thing is true of practically any disease. If one is to master all the pathologicophysiology processes involved in any one disease, he will have covered a great many of the fundamental sciences in medicine. Heart failure is a good illustration of this adage, even though the final word has not been said in a great many of these processes.

This new edition has all the merits of the first one, with the advantage of having been revised and having had the literature brought up to date. This book has already made a place for itself in the literature of cardiology, and is recommended highly to the student of medicine who is not satisfied with a description of disease but wants to get a peep behind the scenes.

*Digest of Laws and Regulations Relating to the Prevention and Control of Syphilis and Gonorrhea in the Forty Eight States and the District of Columbia* Compiled under the direction of Bascom Johnson, A.B., LL.B. 8°, cloth, 438 pp New York. Published and distributed by The American Social Hygiene Association, Incorporated, with the co-operation of The United States Public Health Service, 1940 \$5.00

This essential text for all persons working in the field of public health is arranged by states, which means a subdivision into forty nine chapters, thus making it very difficult to obtain information on a definite point. It could be greatly improved by the addition of a comprehensive index of subjects.

*Plague on Us* By Geddes Smith, M.D. 8°, cloth, 365 pp, with 14 illustrations, and 10 charts New York: The Commonwealth Fund, 1941 \$3.00

This is an excellent book of a semipopular type, based on sound scientific information. The author, associated with the Commonwealth Fund in New York City, has long been active in plague and the general subject of public health. His book covers briefly the entire history of plagues of various types, especially the well known plagues of the middle ages and those associated with definite diseases such as yellow fever, influenza, amebic dysentery, malaria and typhoid fever. Each chapter is written in a pleasant style, with enough slang to make a book of popular appeal. On the other hand, every sentence has been carefully weighed by the author. Sources of his material are given, with numerous references to the literature and splendid illustrations. The illustrations form one of the finest parts of the book, for they have been chosen with great care and bring out historical episodes in man's fight against epidemic disease. This book should be rated in the highest class of popularized medical literature, and it should have a wide appeal, not only to the public but to the more thoughtful person in the medical profession. Accurate and factual, the story, nevertheless, is invigorated by the style of a novelist, and

at once the old cliché comes to mind that "truth is stranger than fiction."

*Multiple Human Births: Twins, triplets, quadruplets and quintuplets.* By Horatio Hackett Newman, Ph.D., Sc.D. 8°, cloth, 214 pp., with 24 illustrations. New York: Doubleday, Doran and Company, Incorporated, 1940. \$2.50.

The distinguished author of this book records a special study of twins and supertwins made over a period of twenty-five years. It is written expressly for the general reader, with admirable success as to style and to human interest. Much of the material goes back to discussions of the heredity-environment problem at a round-table meeting attended by Professor Frank N. Freeman, an educational psychologist, Professor Karl J. Holzinger, an educational statistician, and the writer, a specialist in the biology of twins.

The author begins his book with a consideration of facts, fancies, fallacies and fiction about twins and then leads the reader to an understanding of the causes, varieties, psychology, intelligence and personality traits of twins. The closing chapters deal illuminatingly with the question of twins and the heredity-environment problem. The entire book is handled in a strictly scientific manner. The author concludes that much remains to be done on this extremely complex problem, although he has been successful in untangling some of the threads in that very intricate mesh that constitutes the organism we call man. Every library, general and special, should find a place for this intensely interesting book on its shelves.

*Psychiatry for the Curious.* By George H. Preston, M.D. 8°, cloth, 148 pp., with 17 sketches. New York: Farrar and Rinehart, Incorporated, 1940. \$1.50.

This clear, concise and amusingly written book will undoubtedly prove to be a useful addition to the class of medical literature that physicians can safely recommend to literate laymen; in fact, some psychiatrists could probably read it with profit. After six introductory chapters dealing in simple terms with psychopathology, the author covers briefly but adequately the major psychiatric syndromes and concludes with a short chapter on treatment. Among the most satisfying features of the book are the technically crude but extremely effective line drawings by the author at the beginning of each chapter; they possess a wild Thurberesque quality that not only sets the tone for each chapter but adds a whimsical touch too infrequently encountered in psychiatric literature, lay or professional.

*Legal Guide for American Hospitals: Prepared in collaboration with the Council on Government Relations of the American Hospital Association.* By Emanuel Hayt, LL.B., and Lillian R. Hayt, M.A., J.D. 8°, cloth, 608 pp. New York: Hospital Textbook Company, 1940. \$5.00.

This book is exactly what its title suggests, and is an invaluable reference book for the hospital administrator or trustee. It not only sets forth the general principles governing the formation, organization and the activities of various hospital departments but also cites legal examples that well illustrate the basic principles. Although a fairly large volume, it is divided into chapters relating to the different subjects, which are not unduly lengthy; in fact they are admirably condensed and yet cover all the points involved. It is by far the best legal reference book for hospitals that has been published to date.

*Psychiatric Social Work.* By Lois Meredith French. 8°, cloth, 344 pp. New York: The Commonwealth Fund, 1940. \$2.25.

For many years the need for such a book as this has been recognized by social workers, psychiatrists, educators and others interested in this field. The author's presentation of the origin, growth, definition, analysis and interpretation of the work, as well as its function in hospitals, clinics, educational institutions and public-health organizations, appears to give a complete description of all psychiatric social work. It is regrettable that the book does not fulfill its objectives in all respects. For example, mental deficiency is a great and growing problem and is proving to be a fertile field for psychiatric social work, but is entirely overlooked by the author. Likewise, clinics are described in detail, yet the Massachusetts traveling school clinics, which examine over nine thousand problem and retarded school children each year, are not mentioned.

The trends in social treatment over the past twenty years, present changes and developments and indications of trends for the future are outlined. The report of progress shows that the work of psychiatric social workers has gradually become more definite and clear cut. The training programs set up by schools of social work indicate the same tendency. Psychiatric social work has become definable in two different ways: either, "social work practised in relation to psychiatry," or "social work with emotional difficulties in any setting." The American Association of Psychiatric Social Workers affirms the former.

Although there is much material necessary to make this book a complete study of psychiatric social work, omissions are excusable when it is remembered that this is the first book of its kind. It is worthy of the attention of all who are a part of, or interested in, psychiatric social work.

*Science and Seizures: New light on epilepsy and migraine.* By William Gordon Lennox, M.D., Sc.D. (Hon.). 8°, cloth, 258 pp., with 10 illustrations. New York: Harper and Brothers, 1941. \$2.00.

The interest of the public in epilepsy has been growing markedly in the last few years. This growth is in large part due to the energy of the author of this book, who has been in the forefront of both investigation of the disease and promulgation of the measures to ameliorate the social status of sufferers from epilepsy. He is now president of the International League Against Epilepsy, vice-president and a very active member of the Laymen's League Against Epilepsy and secretary of the Harvard Epilepsy Commission. Dr. Lennox, moreover, has been active in the development of the new science of electroencephalography, a type of research that has thrown a great deal of light on the mechanism of epileptic seizures and particularly of the hereditary aspects of the disease. With this in mind, he has written a book for popular consumption based on a sound scientific knowledge of epilepsy, in addition to an unusual ability to state in clear language, easily understood by the layman, the somewhat complicated story of epilepsy as it is viewed today by the scientific worker. The book is essentially sound and can safely be put in the hands of any patient with this disease. Moreover, it should have a wide appeal to the public. Any profits that accrue from the sale of this book revert to the Laymen's League Against Epilepsy.

## NONARTERIAL DISORDERS SIMULATING DISEASE OF THE PERIPHERAL ARTERIES\*

EDWARD A. EDWARDS, MD†

BOSTON

THE clinician who suspects the presence of arterial disease in a patient's limb can usually make a positive diagnosis of such involvement. Occasionally, however, a disorder in some distant structure is responsible for the presenting symptoms, either through a direct action on the blood vessels of the extremity, or entirely independently of them. It is the purpose of this paper to call attention to the more frequent types of such distant lesions that cause difficulty in the differential diagnosis.

### DISORDERS SIMULATING CHRONIC ARTERIAL DISEASE

The chief chronic organic disorders of peripheral arteries are arteriosclerosis and thromboangiitis obliterans, whereas the vasospastic disorder known as "Raynaud's disease" is the most important functional derangement.

The diagnosis of organic arterial disease depends considerably on the evidence of the diminution in arterial blood flow, which has been summarized<sup>1</sup> as follows: muscle action is weak, and intermittent claudication may develop; the limb is abnormally cold; hypesthesia, hyperesthesia and spontaneous pain may be present; there is diminished resistance to injury, and ulceration may result from slight trauma; the toes and feet show blanching on elevation, and rubor on dependency; and the pulsation in the affected arteries is either slight or absent.

Raynaud's disease is characterized by spasmodic attacks of coldness, with blanching or cyanosis in the fingers and toes, on exposure to cold. The major vessels are not affected, and the major pulses remain normal. The etiology of this infirmity is uncertain, some authorities attributing

it to hyperactivity of the vasomotor system, others to a local vessel fault; but it will be here classified as a vascular disorder, from which other cases of vasospasm will be differentiated.

A great variety of conditions may resemble true arterial disease.

### *Arthritis*

The pain of spinal arthritis commonly radiates down the upper and lower extremities. Von Bechterew,<sup>2</sup> in 1899, pointed out that the pain of arthritis may be due to the pressure of inflammatory exudate on the spinal nerves or their roots. In 1916, Nathan<sup>3</sup> demonstrated, in experimentally produced arthritis, thickening of the vertebral bodies pressing on the spinal cord, and the infiltration of exudate in and about the vertebral articulations encroaching on the nerve roots or trunks in the intervertebral foramina. It is probably justifiable to assume that such lesions occur often in arthritic patients.<sup>4, 5</sup> This thesis is further strengthened by the amelioration of neuritic symptoms after the application of spinal traction.<sup>6</sup>

In arthritis of the cervical spine, the neuritic symptoms may resemble those of Raynaud's disease or of cervical rib disease.<sup>7</sup> Tingling of the fingers, often accompanied by hypesthesia and pallor, is apt to be the predominating symptom. In addition, poorly localized pain is usually present in and about the shoulder and in the entire extremity. These symptoms are often intensified by placing the limb in certain positions, which vary with the patient. An outstanding complaint is that the symptoms increase with recumbency and are intensified when the patient awakes in the morning.

Vascular disease may be further suspected because of coldness of the fingers and actual reduction in pulse volume (Fig. 1). The cervical nerves receive their sympathetic fibers beyond the inter-

\*From the Joseph H. Pratt Diagnostic Hospital and the Department of Surgery, Boston City Hospital. This study was aided by a grant from the Charlton Fund for Research, Tufts College Medical School.

†Instructor in anatomy, Harvard Medical School; instructor in peripheral vascular diseases, Joseph H. Pratt Diagnostic Hospital.

vertebral foramina; therefore, direct pressure on them or their roots cannot account for the vasospasm, but it may be a reflex from the joint irritation (Fig. 2). Dr. Thomas H. Peterson, in a personal communication, states that in such cases the application of head traction may cause a fall in the diastolic arterial pressure in the limb, with

in the cervical spine in the roentgenogram is, of course, significant.

CASE 1. A. T., a 40-year-old married woman, was referred for disagreeable prickling sensations in the fingers of both hands, associated with coldness and sweating. The onset was gradual in the early autumn and had lasted for 1 month prior to examination. The diagnosis of Raynaud's disease was considered, especially since two of the patient's sisters had disorders of this type. Further questioning elicited the fact that the prickling was present during the night, and was particularly troublesome when the patient awoke in the morning. She recalled no changes in the color of the hands. Likewise, there was no association of the attacks with exposure to hot or cold air or water.

Examination showed cold sweaty hands and fingers. There was no discoloration, deformity or trophic change, and sensation was grossly normal. Both radial pulses could be easily palpated, but the Pachon oscillometer showed a slightly diminished pulse expansion at the wrists, consistent with some vasoconstriction. Motion of the neck was full in all directions. Roentgenograms of the cervical spine showed a hypertrophic arthritis, with calcification of the intervertebral ligaments.

The patient received immediate benefit from diathermy treatment of the cervical spine. Recurrence of symptoms was expected, however, with any reactivation of the arthritis.

If arthritis attacks the lumbar spine, symptoms are experienced in the lower limbs, analogous to those described above. The pain does not often lie along the sciatic nerve, but is apter to be found in other regions of the limb. In the foot, it may be accompanied by hypesthesia and paresthesia, an association strongly suggestive of arterial insufficiency. More typical, however, is poorly localized pain in the thighs. This is ordinarily not diminished on activity, and occasionally its exacerbation on walking may be associated with cramps, which differ from those of true intermittent claudication in their location and lack of regularity. As in the upper extremity, vasoconstriction may be marked. It is noteworthy that the symptoms are by no means necessarily bilateral.

CASE 2. S. G., a 62-year-old tailor, complained of coldness and pain in the left lower leg. Fourteen years previously, he had an attack of severe pain in the left foot and ankle, necessitating bedrest for several weeks. Three years before, he had a recurrence of the pain, which disappeared after massage. Three months before the patient was seen, the pain again returned. It was described as a "drilling" or "pressing" in the left foot and ankle, and was initiated by standing or walking. Walking was indeed almost impossible, since the pain forced the patient to stop for a few minutes' rest about every 25 feet. The discomfort disappeared immediately on resting. He also described an additional, more constant pain throughout the thigh, which was increased on recumbency. The patient refused to stay in a supine position on the examining table, because it induced cramps in his left thigh. It was brought out that these cramps frequently occurred at night.

FIGURE 1. The Brachial Blood Pressure in a Patient with Cervical Arthritis. (Courtesy of Dr. Thomas H. Peterson.)

Pain radiating into the right upper limb occurred at A, and in the left limb at A'. The blood pressure was high on the affected side during the attacks of pain, presumably because of vasoconstriction in the distal parts of the limb.

a corresponding increase in the amplitude of the pulse.

Symptoms are not always present in the neck. Likewise, clinical examination may not reveal any abnormality there. Thus Turner and Oppenheimer,<sup>7</sup> in their reported group of 50 patients, most of whom, at least, were arthritic, found only 2 who complained of pain in the neck, and only 2 who had restriction of cervical motions. The history is nevertheless of extreme importance, inasmuch as the patients do not suffer most on exposure to cold air but, contrariwise, may be most uncomfortable in bed when the extremities are adequately warmed. The joints of the fingers may or may not show arthritic changes. The finding of either atrophic or hypertrophic changes

Examination showed coldness of both feet, with the surface temperature of the left foot  $3^{\circ}\text{C}$  below that of the right. There was no blanching on elevation, and no rubor on dependency. All the arterial pulsations were palpable, with the exception of that of the left posterior tibial artery. The Pachon oscillogram showed a diminished pulse amplitude, the reading of the right ankle being 25 units, that of the left 20 units. The spine showed a loss of the normal anterior convexity of the lumbar region with an extreme right dorsal, left lumbar scoliosis,

in severity, back exercises were instituted. After the ninth treatment, he felt greatly relieved, and diathermy was discontinued.

If the arthritis involves the joints of the limb, it is usually a simple matter to avoid its confusion with vascular disease. In cases of pain in the foot, for example, immobility on manipulation may point to involvement of the small joints of this

FIGURE 2 Pathways for Vascular Reflexes Originating in the Limb (modified after de Takats<sup>1</sup>)

Afferent impulses can arise in any of the tissues including bone joint skin artery and vein. The stimuli travel by way of the sensory fibers of the spinal nerves (solid line) to reach the cells of the intermediolateral column of the cord. These cells (\*) represent a 'final common path' of the sympathetic system since they receive impulses from all levels of the nervous system and send their processes outward to the sympathetic ganglia. Postganglionic fibers conduct the efferent impulses to the arteries and veins (constriction) as well as to the sweat glands and arrector pili muscles. Some sensory fibers of the spinal nerves (broken line) conduct afferent impulses from the skin or deep tissues and through an axon reflex give rise to the efferent response of vasodilatation in the capillaries of the extremity.

but good flexibility. X-ray examination showed prominent spurs at the margins of the lower dorsal and lumbar vertebrae, with calcific bridging of the 1st lumbar intervertebral space. The hip joint likewise showed hypertrophic changes.

The patient was placed on a high vitamin, low-carbohydrate diet, and diathermy treatment was given to his spine. The feet became warmer, and the pulses increased somewhat in amplitude. After four such applications, the patient could lie flat on his back without cramps in the thigh, and the symptoms on walking had diminished

part. Arthritis of the knee may cause pain radiating into the calf. Here one should recall that the pain of an arthritic knee is usually worse on arising, but diminishes with moderate use. Examination will show periarthritic thickening, with or without crepitus and pain on motion.

Decision is difficult when the pain is increased by walking, particularly if it is cramplike. This is perhaps seen oftener when the arthritis involves

the hip. As in spinal arthritis, this cramp is differentiated from that of true intermittent claudication by its irregularity in time and in degree of severity. Clinical examination may not demonstrate disability in the hip joint, but involvement of the more accessible joints points to the diagnosis, and the roentgenogram may be of great aid.

CASE 3. L.S., a 40-year-old housewife, was referred for pain in the lower extremities of 1 year's duration. The pain appeared in both ankles while the patient was walking, but it was less troublesome there than in the upper medial part of the left thigh, where it was cramp-like. The patient had to stop and rest because of the pain, but the distance traversed between rest periods varied from time to time and day to day.

Examination of the lower extremities showed strong pulsations in all the arteries. The saphenous veins were moderately dilated, and some valvular incompetence was manifest. There was a little loss of mobility in the feet, but no evidence of arthritis in the knees or back, or in the joints of the upper extremities. Extremes of hip motion reproduced the crampy pain in the left thigh. Roentgenograms of the hip joint showed hypertrophic changes. The patient's symptoms were attributed to the arthritis of the left hip, and improvement was obtained by treatment similar to that mentioned in the previous case.

### *Diseases of the Nervous System*

Lesions of any part of the nervous system, from the brain to the finer nerve branches, may mimic chronic arterial disease. As a well-known example, one may mention the cold and cyanotic extremities in the chronic stage of anterior poliomyelitis, and in the catatonic type of dementia praecox.

The simulation to arterial disease is frequently brought about independently of any known vascular change. In these cases, it may be especially confusing if trophic ulceration is present, since ulceration often has its origin in intrinsic vascular disease. Medical writers have unfortunately caused some confusion by using the term "mal perforans" for any perforating lesion of the foot or toe, regardless of the etiology. The presence or absence of sensitivity in such a lesion is, happily, an excellent guide to its true etiology. When the ulcer is of vascular origin, there is usually severe pain. The trophic ulcer of nervous origin, on the contrary, is usually located in a zone of hypesthesia or anesthesia. A determination of the neurologic state of the limb and the patient, on the one hand, and the vascular state, on the other, allows one to establish the correct diagnosis.

CASE 4. M.M. (Boston City Hospital No. 79470), a 39-year-old laborer, was first seen at the outpatient department of the hospital for a septic callus over the plantar surface of the left 5th metatarsal. Amputation of the 5th toe and head of the metatarsal was performed because of the presence of osteomyelitis.

Six months later, the patient developed an ulcer on the plantar surface of the left great toe (Fig. 3). The foot was cold, sweaty and cyanotic, findings that suggested an underlying vascular lesion; both the dorsalis pedis and posterior tibial pulses were normal, however. The plantar surface of the toe, including the base of the ulcer, was so anesthetic that the underlying bone, which was carious, could be probed without producing the slightest pain.

Further questioning revealed that the patient had fallen down the hold of a ship and injured the spine, 12 years previously. He was treated by a plaster cast, then by a

FIGURE 3. *Mal Perforans of the Great Toe.*

*In this patient (Case 4), the condition was associated with injury to the lumbar nerve roots following a compression fracture of the spine, but the peripheral arteries were normal. Carious bone was present in the floor of the ulcer. The fifth toe had previously been amputated for the same disorder.*

brace, for 2½ years. From that time on, he had no symptoms until the onset of the present illness. He admitted some dribbling of urine for 3 weeks prior to the last examination, but no rectal incontinence and no impotence.

X-ray examination showed an old compression fracture of the body of the 2nd lumbar vertebra, with bony union between it and the body of the 1st lumbar vertebra.

There was hypesthesia of the body on both sides below the distribution of the 1st lumbar nerves. The knee jerks were diminished on the right side, and the ankle jerks were absent. There was a positive Babinski reaction on the left side. A laminectomy was performed by Dr. Walter Wegner. There was demonstrated a considerable mass of scar tissue, both fibrous and bony, at the level of the 1st and 2nd lumbar vertebrae, involving some of the anterior and posterior roots of the cauda equina. The scar tissue was removed, some of the roots being unavoidably injured during this procedure. The symptoms gradually regressed after operation, and the ulceration of the foot healed after several months.

Peripheral neuritis of various forms may simulate arterial disease even when unaccompanied by ulceration. This is due in part to the presence of pain in the limbs, and in part to coldness incident to vasospasm. In this connection, Lewis and Pickering<sup>8</sup> state:

The chief cause of lowered skin temperature after mixed nerve lesions is loss of the fibers belonging to the posterior root system. While it is probable that this loss is effected chiefly through the disappearance of the sensory axon reflex [normal vasodilatation mechanism], we are unable to exclude the possibility

that loss of vasodilator impulses passing from the cord by posterior root fibers may also play a part (See Fig 2)

Dole and Morison,<sup>9</sup> however, could find no evidence for the existence of the second mechanism mentioned

CASE 5 L J, a 42-year-old jeweler, was referred for cramps in the feet and calves of 8 years' duration. The cramps came mostly at the close of any day that required much standing. On some occasions, they appeared while the patient was standing and could be relieved by walking; whereas at other times, they came on only after traversing a block or two. For 3 years before consultation, the patient was troubled by this symptom at night, which necessitated his getting out of bed for a few seconds, when the cramps disappeared. The patient's malady was worse in the 3 weeks prior to the examination, a fact attributed to a temporary increase in work. Additional evidence was secured that the patient had been a fairly hard drinker for many years. During the month preceding examination, he had taken several drinks a day and finally had been confined to his home for several days because of alcoholism. He had become extremely apprehensive and had entertained some delusions. His diet was admittedly poor, with a minimum of fresh vegetables. He had begun smoking at the age of 16 and, at the time of examination, smoked ten to fifteen small cigars a day. Chronic otitis media and mastoiditis were present and possibly operated as additional toxic factors.

Examination showed moist, cold feet. There was no discoloration and no blanching on elevation. The femoral and popliteal pulses were excellent. Although neither dorsalis-pedis pulsation could be felt, the posterior tibial pulses were of excellent quality. The oscillometer showed small but equal pulse expansions at the ankles. There was some superficial tenderness on the dorsum of the feet and a little extensor weakness. Both feet were in moderate pronation.

It was believed that the coldness and sweating represented vasomotor symptoms due to an alcoholic neuritis or, possibly, to the patient's smoking. Relief from the cramps was obtained by an increase in vitamin intake, a reduction in smoking and measures directed to pronation of the feet, namely, the use of orthopedic heels and foot exercises.

So-called "ganglionitis" and "radiculitis" are troublesome variants of peripheral neuritis.<sup>4, 6</sup> The presenting symptom usually is intractable pain in the foot or leg, which on close questioning is characteristic of a hyperesthesia. The symptoms vary according to whether the posterior or anterior roots, or both, are involved. Examination may disclose areas of hyperesthesia or anesthesia, with muscle weakness and abnormal deep reflexes. The majority of cases occur in the lower extremity.

CASE 6 C H, a 57-year-old housewife, was referred because of pain and coldness of the right foot, and cramps of the right calf, of several years' duration. There was fairly constant pain and blanching in the 2nd toe. The remainder of the foot was cold and blanched spasmodically especially in cold weather. The patient avoided walking because of heaviness in the leg. This symptom

was usually not accompanied by cramps, which were apt to appear at night. The patient believed that at least some of her symptoms dated back 39 years to an attack of herpes zoster that had involved the right lumbar region.

Examination of the lower limbs showed normal cutaneous color in all positions. Both feet were cold however, the right more than the left. The right dorsalis-pedis pulse could not be felt but its absence was apparently adequately compensated for by a palpable peroneal and a large posterior tibial pulse. The left dorsalis pedis and posterior tibial pulses were forceful. Oscillometric examination showed good arterial pressure and pulse amplitude at both ankles.

In contrast to its normal vascular status the limb showed abnormal neurologic findings. The patient was transferred to the care of Dr Tracy J Putnam, whose findings were as follows:

Motor power was good in both legs and both feet, the right ankle jerk was more active than the left, however, and there was a suggestion of clonus on the right. The Babinski reaction was negative on both sides. There was hyperesthesia over an area of the dorsum of the right foot centering around the 2nd toe and plantar surface of the 2nd and 3rd toes. The hyperesthesia was most marked to pinprick. There was a loss of vibratory sense in the ankle but no loss of position sense. There was no tenderness of the sciatic nerve, but there was tenderness of the lower spine. Small scars in the mid line were suggestive of an old herpetic eruption.

It seems to me that the diagnosis must be a chronic progressive neuritis. In view of the old history of pain, the long-continued subjective heaviness of the right leg and the hyperesthesia this must have affected the whole sciatic nerve to some extent, but is most intense in the peroneal branch. I believe that it is a result of the old herpes.

According to Dr Putnam's suggestion, the patient was given deep x-ray therapy over the roots of the sciatic nerve. After ten treatments, she experienced complete relief from her symptoms.

A more puzzling interplay of neurologic and vascular symptoms is present in the syndrome of causalgia, resulting from injuries to the large nerves, especially the median and sciatic. The symptoms, which are disagreeable and disabling, consist in extreme hyperesthesia, with coldness, cyanosis and sweating.<sup>10, 12</sup> Similar disorders of less severe degree may follow almost any injury in any part of the extremity. Such cases following a fracture, sprain, puncture wound or mild infection have been described by several authors.<sup>11-13</sup> As emphasized by de Takats,<sup>17</sup> this category of reflex dystrophy of the extremities includes syndromes designated as reflex vasoconstriction, traumatic osteoporosis, traumatic arthritis and so forth. Common to all such disorders is an irritation of a sensory nerve or its endings, which sets up reflexes mediated by the sympathetic fibers with an effector response in the blood vessels (Fig 2). The sweat glands and arrector pili muscles may also react, thus giving rise to locally

excessive sweating and to an exaggerated pilomotor ("goose-flesh") reaction. Homans<sup>18</sup> adds a theory that some of the sensory changes are due to the interference with the nutrition of the larger nerve trunks caused by the reflex vasoconstriction of their nutrient arteries.

When a diminution in blood flow results from such disorders, it becomes necessary to rule out organic obstruction of the arteries, which indeed may have been produced by the primary injury to the limb. The decisive data are obtained by

FIGURE 4. *A Vasodilatation Test in a Patient (Case 7) with Vasospasm Secondary to a Scar Neuroma of the Ring Finger.*

*Immersion of the opposite extremity in warm water resulted in a pronounced vasodilatation of the affected finger and a rise in the skin temperature to a level at least as high as that of the normal first digit. The test established that the diminution in blood flow was reflex in nature and ruled out organic disease of the peripheral arteries.*

inhibiting the vasomotor control of the vessels.<sup>19</sup> The uninvolved extremities may be immersed in hot water at 43°C. (Landis-Gibbon test), or spinal anesthesia may be induced for the lower extremities and paravertebral sympathetic anesthesia for the upper extremities. If the diminution in blood flow depends entirely on vasospasm, without any organic vascular obstruction, the sympathetic inhibition allows a considerable increase in blood flow to occur. This effect can be measured by determining the skin temperature or the oscillometric index of pulse expansion, before and after the test (Fig. 4).

When one is dealing with a reflex effect, relief will be obtained if the irritable focus can be ex-

cised, as in the case described below, or if the reflex can be interrupted, as by sympathetic ganglionectomy.

CASE 7. M. A. H., a 29-year-old factory worker, was seen for pain and coldness of the right ring finger. Seven months prior to consultation, a sliver of steel had passed under the nail, and the finger had become infected. The finger tip was incised under procaine block at the base of the digit, and under general anesthesia on two more occasions. Immediately after the last incision, the finger became white, cold and painful. The pain was constant, necessitating sedation at night. The slightest touch of any part of the finger resulted in intense pain, and the symptoms were likewise increased on exposure of the hand to cold. The patient was not working. He was depressed mentally, and had lost 18 pounds.

Examination showed the finger to be blanched from base to tip. Both this digit and the little finger were strikingly cold, the temperature being 2.5°C. below that of the other digits. An exquisitely tender scar, 8 mm. long, was present on the tip of the injured finger, but the hyperesthesia extended beyond this zone onto both surfaces of the finger to its base. The pulses at the wrist were normal to palpation and by oscillometric measurement.

The obvious marked diminution in local blood flow brought up the possibility that the digital arteries had been thrombosed during the infection, or by the digital nerve block. To determine whether the vessels were thus obstructed, the cutaneous temperature of the fingers of the right hand was measured before and after immersion of the normal left hand and forearm in hot water. Adequate vasodilatation resulted (Fig. 4). The digital arteries were therefore not organically blocked but, on the contrary, were in a state of vasoconstriction, apparently secondary to the tender scar of the finger tip.

Excision of the scar resulted in the complete disappearance of the disorder.

### Phlebitis

It is known that phlebitis is often accompanied by vasospasm, manifest by small pulses and coldness in the extremity, and may thus resemble a primary arterial disorder.<sup>20</sup> It is quite evident that, from the standpoint of the mechanism of this vasospasm, phlebitis is, like the other conditions considered above, one particular source of sensory irritation that is adequate to set off vasoconstrictor responses.

In a previous report,<sup>20</sup> it was emphasized that the arteries are but one of several structures in the limb that, because they receive sympathetic innervation, are all equally liable to react to venous irritation. These structures include the veins, the sweat glands and the arrector pili muscles (Fig. 2). Therefore, if arteriospasm is present, it may be associated with sweating of the cold extremity and an abnormally active pilomotor reflex ("goose-flesh").

Severe arteriospasm giving loss of the major pulses may occur, but is much less common than minor degrees of vasoconstriction. To establish

the true nature of the disturbance, one must look for the typical tender induration of the phlebitic vein, and the cyanosis and edema on standing. Phlebitis may further be suspected as the cause of the diminished arterial flow if there are accompanying sweating and increased pilomotor response. The latter reflex is easily tested by pinching the skin of the extremity, or by touching it with a cold object. Finally, one should be able to demonstrate that the blood flow can be increased, after sympathetic release, by one of the methods described in the preceding section.

CASE 8. M. P., a 40-year-old married schoolteacher, was referred for pain and coldness of the right foot, following a fracture of the 5th metatarsal bone. These symptoms were constant, and increased on standing or walking, when they were accompanied by cyanosis and edema of the limb. For some months prior to the accident, the patient had noticed cramps, which appeared during the night but not while she was walking. With this history in mind, and because no pulsations could be made out in the pedal arteries, her local doctor had suspected arterial disease and had treated the patient by injections of a pancreatic extract (Depropanex). At the end of 2 weeks' bedrest, the swelling diminished but the extremity was still painful and cold.

On examination, the right calf showed 13 cm of atrophy. There were moderate cyanosis and coldness in the lower leg, foot and toes. The toes blanched slightly on elevation. There was no excessive sweating, but the pilomotor response was exaggerated. The femoral and popliteal pulses were of good quality, and although the pulsation of the dorsalis pedis artery could not be felt, that of the posterior tibial artery was fair. On the unaffected left side, the pulsations were approximately the same, with a nonpalpable dorsalis pedis but a slightly larger posterior tibial pulse. Moderate edema was present on the medial side of the affected ankle, and a tender thickening could be felt along 12 cm of the course of the saphenous vein in the lower calf. There was but minimal tenderness over the 5th metatarsal bone, and an x-ray film showed good healing of the fracture.

The nocturnal cramps preceding the injury were presumed to be due to a varicose widening of the saphenous vein. This was borne out by the discovery of a dilated vein at operation. The tenderness over a segment of the vein, in addition to the cyanosis and edema, pointed to a phlebitis that might have started in the deep veins following the primary trauma, with subsequent extension to the saphenous vein. The coldness and exaggerated pilomotor response were consistent with a sympathetic reaction from the phlebitic vein.

A ligation of the saphenous vein was performed under spinal anesthesia. Skin temperature and oscillometric readings showed adequate vasodilatation after the anesthesia and operation, a finding indicating that there was no organic obstruction of the arteries. Conversely, the experiment strengthened the conclusion that the coldness of the extremity was due to a vasospasm, presumably secondary to the phlebitis.

The symptoms quickly diminished. Small areas of thrombophlebitis appeared in the superficial veins of the thigh. Radiant heat and diathermy were given to the limb, and active exercises were started. On discharge, the same treatment was continued by the family physician, and the symptoms regressed satisfactorily.

### *Cervical Rib, Anomalies of the First Thoracic Rib and the Scalenus Syndrome*

Although cervical rib is usually included in a classification of vascular disease, it is more properly considered as a condition that simulates primary arterial disease.

The symptoms can be both neurologic<sup>21</sup> and vascular, and may be constant or spasmodic. The patient usually complains of numbness and tingling in the limb, especially along the medial side of the forearm and hand and in the more medial fingers. Muscular weakness and wasting may occur in the hypthenar muscles or, less commonly, in the thenar group. True vascular symptoms are infrequent. They include episodes of blanching or cyanosis of one or more fingers or of the entire hand. Both sets of symptoms occur, especially in relation to muscular effort or to changes in position of the neck or the extremity. Exposure to cold may inconstantly initiate an attack. The blood pressure may be lowered on the affected side, and the radial pulse may be small and, very rarely, obliterated. Pain may be felt in the neck, radiating into the shoulder. If the rib is large, there may be a visible elevation. In some cases, the subclavian pulsation is more prominent than normal; this happens most frequently when the rudimentary rib belongs to the first thoracic segment.<sup>22</sup>

It is apparent that the neurologic symptoms are caused by the impingement of the lower trunk of the brachial plexus on the cervical rib<sup>21-23</sup> (Fig 5). Todd<sup>25</sup> and others<sup>26-27</sup> believe that vascular symptoms, when present, are caused by the concomitant irritation of the sympathetic fibers in the trunk, whereas Lewis and Pickering<sup>28</sup> and others<sup>29</sup> conclude that these symptoms depend on actual contact of the rib and the subclavian artery. Murphy<sup>30</sup> suggested that the scalenus anterior muscle, placed in front of the artery and nerve, plays a role in the production of symptoms by pressing these structures against the rib. This thesis was reaffirmed by Adson and Coffey.<sup>31</sup>

It is worth remembering that an abnormal first thoracic rib may give rise to symptoms identical with those of a cervical rib.<sup>22-23</sup> Finally, there is a much larger group of patients, with the signs of cervical rib, who show no bony anomalies.<sup>34-37</sup> Here, as in cervical rib, symptoms are apparently caused by injury to the lower trunk of the brachial plexus as its component from the first or first and second thoracic nerves arches upward and outward over the first rib to gain the limb (Fig 5). An exaggeration of the downward slope of the shoulder (especially pronounced in women) may initiate, or at least aggravate, this irritation. Niff

CASE 11. A 46-year-old man entered the hospital because of pulmonary embolism resulting from a phlebitis in the deep veins of the right leg. Within the next two weeks, the phlebitis ascended to the right femoral and iliac veins. This was followed by sudden pain in the left groin and inability to move the extremity. The left leg was cold, dry and anesthetic to the knee. Above, it was hyperesthetic. Before this episode, all the pulses of the leg had been palpated and found to be normal, but shortly thereafter no pulsation could be detected in any of the vessels from the femoral artery downward.

The symptoms disappeared and the pulsation returned in full force within 45 minutes after the application of heat.\* Induration of the left femoral vein was then apparent, and dilated superficial veins were visible in the left flank.

### *Disease of the Central Nervous System*

It has already been shown how diseases of the nervous system, both central and peripheral, may simulate chronic arterial disorders. The following case report is considered of particular interest, since an acute spasm of a major artery was induced by an intermittent disorder of the brain. It is possible that the cerebral cortex was involved in this reaction, since reported experiments indicate that the central and precentral areas of the frontal lobe are concerned in vasomotor control.<sup>39</sup> Peet and Kahn<sup>40</sup> report syndromes similar to Raynaud's disease that are incident to cerebral lesions, and refer as well to examples of the loss of a peripheral pulse during operative manipulation of the brain.

CASE 12.<sup>†</sup> J. J. (Boston City Hospital No. 800477), a 34-year-old woman, 19 days after a nephrolithotomy, suffered a sudden attack of transient numbness and weakness of the entire left side of the body, with a persistent right homonymous hemianopsia. Because of a previous history of rheumatic heart disease, this incident was ascribed to a cerebral thrombosis or embolism. One week later, the patient was seized with a sudden knifelike pain in the left groin. The limb was numb, palsied and cold, and the resemblance to arterial embolism was further increased by the absence of the femoral pulse. Operative exploration revealed a tightly contracted femoral artery, the pulsation of which, however, returned when it was stripped from its sheath. No embolus was found on incising the artery, and following operation the pulses returned in the extremity.

I saw the patient through the kindness of Dr. Tracy J. Putnam, to whose service she was transferred. Determination of the vascular status of the lower extremities showed small but probably normal pulsations; those on the left side were only slightly weaker than those on the right. The variation was of a magnitude often seen in normal extremities.

During the remainder of her hospital stay, the patient suffered attacks of probable cardiac asthma associated with occasional incidents of numbness and weakness of the left side of the body. In some of these attacks, the pulses of the lower leg disappeared and the retinal arterioles be-

came constricted. A similar attack, of greater severity, was induced by an intravenous injection of Ergobasine. Again the left femoral pulse disappeared, and the retinal vessels were seen to be constricted. The symptoms gradually wore off after the inhalation of carbon dioxide and oxygen.

Although certain aspects of the case pointed to the presence of hysteria, at least as a complicating factor, the consensus was that in the spontaneous episodes the patient had suffered from a cerebral and ophthalmic arteriospasm, which was associated with a spasm of the vessels of the left lower extremity. It was thought that this process had been repeated during the induced attack.

### SUMMARY

Chronic disease of the peripheral arteries, as well as acute thrombosis and embolism, may be simulated by a great number of disorders in the other tissues of the extremities or in quite distant organs. The mechanisms whereby the confusing symptoms are produced are discussed, and several case reports are cited to illustrate the methods of differential diagnosis. These cases include arthritis of the cervical and lumbar spine and of the hip joint, a cauda-equina lesion from an old compression fracture of a lumbar vertebra, ganglionitis, peripheral neuritis, scar neuroma, phlebitis, cervical rib and the postirradiation state. Peripheral arterial embolism was suspected in a patient with phlebitis and in one with probable cerebral arteriospasm. Doubtless several other diseases could have been represented.

It is apparent that a precisely detailed history usually gives the clue to the correct diagnosis. One must also attend to the general examination and evaluate carefully the condition of all tissues of the limb. Thus, in addition to the condition of the vascular system, the examiner must determine the cutaneous, neurologic, articular, osseous and muscular status. If arterial inadequacy is shown to exist, he must discover whether it is due to organic disease or to vasospasm secondary to some other disorder.

## WHAT SENSIBLE LIVING AND NATURAL RECOVERY CAN DO FOR A CARDIAC PATIENT\*

HARRY B. LEVINE, MD,<sup>†</sup> AND PAUL D. WHITE, MD<sup>†</sup>

BOSTON

IN THESE days of high-pressure sales of medicines and the introduction of new surgical procedures, it is well to pause a bit and consider what may be accomplished by natural processes of healing and by sensible attention to the details of daily life. This observation applies to much of the field of internal medicine and especially to cardiac patients, most particularly those with rheumatic and coronary heart disease.

Much too often, recovery from a serious cardiac ailment is credited to a particular form of therapy, whether oral medication or surgical intervention. Follow-up studies have shown in many cases not only that recovery from an acute cardiac illness has taken place without special therapy, but also that these patients have lived useful lives for many years afterward. Such recovery and longevity, as will later be shown in illustrative case reports, occurs irrespective of the type of therapy instituted.

In a previous communication<sup>1</sup> attention was called to the fact that, although the prognosis

of heart disease in apparently serious and grave cardiac states is often a difficult problem, one should recognize the fact that "functional recovery may be so complete that the ultimate prognosis is good for many years after."

Although one may encounter a patient with what appears to be a mild heart attack who unexpectedly dies, we have seen the reverse in many cases—that is, very seriously ill patients who not only make an immediate recovery but are able to carry on their occupations, with some limitations, for many years. The age of the patient and the type of cardiac disability may play little or no role in the ultimate recovery.

Because of the importance of these considerations and of the frequency with which they are overlooked, we have assembled the records of 7 striking cases illustrative of a great many that we have seen. The types of heart trouble were: rheumatic heart disease with mitral stenosis (2 cases) and coronary-artery disease (5 cases). We have divided the patients into two groups: those experiencing a natural, that is, spontaneous, recovery (3 cases) and those in whom longevity was due, in part at least, to sensible living (4 cases). The term "natural recovery" refers to a return to

\*From the Cardiac Clinics Massachusetts General Hospital

<sup>†</sup>Assistant in medicine Massachusetts General Hospital

<sup>†</sup>Lecturer in medicine Harvard Medical School physician Massachusetts General Hospital in charge of the Cardiac Clinics and Laboratory

health that we could not ascribe to any particular type of therapy.

CASE 1. J. E. K. was first seen in the Cardiac Clinic at the Massachusetts General Hospital in June, 1923, at the age of 13, when rheumatic heart disease with active rheumatic fever was found. In November, when there was no evidence of active (rheumatic) infection, he indulged in football without any ill effects. In April, 1924, because of what was thought to be a well-marked mitral stenosis, he was referred to the Peter Bent Brigham Hospital for valvotomy. Because of the presence of asthmatic bronchitis, operation was deferred. The patient returned to the Cardiac Clinic in 1931 for a check-up; x-ray examination showed marked prominence in the region of the pulmonary conus, with a normal transverse diameter of the heart. The electrocardiogram showed sinus arrhythmia at a rate of 70, with notched P waves in all leads. The findings were consistent with rheumatic heart disease. On October 11, 1934, the patient returned feeling well and without symptoms, and on April 30, 1940, at the age of 30, he again returned to the clinic. Examination showed a healthy appearing man. The blood pressure was 120/75. The pulse rate was 60 and regular. There was no abnormal pulse in the neck. The heart was normal in size. With the patient in the upright position, the only abnormality heard with the Bowles stethoscope was a very slight early diastolic blow at the lower end of the sternum and at the apex; this murmur could easily have been missed. With the bell at the apex, there was a rather loud 1st sound, and a 3rd sound with a very faint rumble following it. With the patient in the recumbent position, the mitral diastolic murmur was louder, with slight presystolic accentuation.

In this case there was no doubt about the presence of a relatively slight amount of mitral stenosis and of a very slight amount of aortic regurgitation, neither of which is apparently a serious burden to the heart itself. The "marked mitral stenosis" noted sixteen years previously was probably largely due to dilatation of the heart secondary to acute rheumatic infection. This patient has done very well, and is lucky to have escaped operation. The case illustrates the extreme care that one must exercise in making a correct diagnosis in the first place, and the natural tendency for the heart to do well for many years after the subsidence of active rheumatic infection.

CASE 2. G. B. D., an 84-year-old man, entered the Phillips House on February 4, 1938, seriously ill, with a story of recent angina pectoris decubitus. The patient, always hale and hearty until old age, had been bothered for several years by a series of illnesses and accidents, beginning about 10 years previously with an automobile accident. Five years before admission to the hospital, he developed glaucoma and cataracts, and 3 years before, swelling of the legs from varicose veins began. There had been no dyspnea or chest pain until the summer of 1937, when he began to have discomfort in the upper chest on both sides of the sternum on effort; this was relieved by rest. The severity of the attacks gradually increased during the fall and winter. Three weeks prior to entry, the patient had been awakened at night by this same ache, which recurred through that night and at intervals on later nights.

He had rested, but not in bed. Examination showed an elderly man, moderately ill, with normal blood pressure (145/80) and pulse rate (60). The heart was enlarged, with a total transverse diameter, by teleroentgenogram, of 17.5 cm. and a chest diameter of 31.0 cm. The electrocardiogram showed auricular premature beats with T<sub>1</sub> upright, T<sub>2</sub> low and T<sub>3</sub> inverted; there was moderate left-axis deviation, a PR interval of 0.20 second, and a normal Lead 4. A gastrointestinal x-ray series was normal.

Because this patient was already improving, without drugs, during the first few days in the hospital, no therapy except rest was prescribed. He improved steadily; in 2 weeks he was able to walk upstairs without symptoms, which he had not been able to do for weeks before, and not long thereafter he returned home free of symptoms *and without medicine*, much to the surprise of himself and of his family and friends.

In June, 1939, a close friend reported that the patient had been well after his return home in the winter of 1938 until the late winter of 1939, when he had a recurrence of his angina pectoris decubitus just like that of the previous year, which again cleared under the same therapy—rest without medicine, this time at home. In the summer of 1940, the patient was reported to be in good condition, even being able to attend evening meetings.

This case illustrates spontaneous recovery from severe coronary insufficiency—probably secondary to coronary thrombosis without infarction—twice at an advanced age. Rest, without drugs, doubtless helped in this recovery. The trouble with the eyes (glaucoma and cataracts) and with the legs (varicose veins) had restricted the patient's activities considerably, which may have prevented earlier symptoms of cardiac distress.

CASE 3. F. J., a stout, 61-year-old banker, in 1935, while sitting in a chair swallowing the first mouthful of a meal, fell unconscious without warning. The syncope lasted a few seconds. The patient had two similar spells in the next 2 days. He was then put to bed for 6 weeks, and reduced his weight from 246 to 226 pounds. An electrocardiogram showed right bundle-branch block but a normal PR interval. Two years later, in August, 1937, the patient fainted again, and thereafter was all right until October, when he began to have frequent attacks of faint spells and syncope. Despite much classic therapy, he continued to do very poorly, and was constantly threatened and actually affected by what was definitely proved to be Adams-Stokes attacks—the electrocardiogram during an attack showed a standstill of the ventricles, with a gradual return through partial grades of block to normal PR intervals. When he was at his worst, in March, 1938, the patient was having several attacks of unconsciousness daily. Physical examination showed no abnormalities, except for moderate obesity, a slight to moderate systolic murmur at the aortic valve area and at the cardiac apex, and occasionally an intermittent pulse, at a heart rate of 84. An electrocardiogram showed normal rhythm at a rate of 60 to 65, with right bundle-branch block and normal PR intervals. X-ray examination showed a full-sized heart, with a somewhat dense aorta.

The patient continued in a precarious state despite the use of atropine sulfate, nitroglycerin, ephedrine and injections of epinephrine hydrochloride intramuscularly—all of which did, however, undoubtedly help him tem-

porarily—during the next year. Finally, because of a critical sinoauricular heart rate of about 75, above which partial block and Adams-Stokes attacks occurred the administration of digitalis was advised. Because of a previous unfavorable experience with digitalis, Urganin was given, and under its influence, in addition to that of adrenalin, he rapidly improved and during the next year and a half was in surprisingly good health, completely free from any attacks of Adams-Stokes syndrome.

Physical examination in November, 1940, showed moderate hypertension (200/90), a moderately enlarged heart with harsh aortic and moderate apical systolic murmurs and no evidence of congestive failure. On fluoroscopic examination, there was moderate enlargement of the heart, with clear lungs. The electrocardiogram showed complete auriculoventricular block, with an auricular rate of 85, a ventricular rate of 40 and bundle branch block as before. The patient had reduced his weight to 216 pounds, and was quite active again, having resumed his regular work, though not intensely, at the age of 66 years.

This patient showed a hopeful recovery from partial auriculoventricular block with Adams-Stokes syndrome. The transition to complete heart block was doubtless spontaneous and accounts more for his present state of good health than the drug therapy does. However, it is probable that the drugs helped him over a critical period. Although his duration of life is uncertain, it is hoped that he may continue in his present fair state of health for some years to come. We have encountered similar patients who have survived for ten years or more after the establishment of complete heart block.

The effect of sensible living, not only on the well-being but also on the longevity of the patient, is clearly demonstrated in the following group of cases. To prescribe drugs and to advise certain surgical procedures in many cases of heart disease are not only advisable but at times essential and useful. However, one should define to his patients, clearly and forcibly, the importance of personal readjustment to individual needs. Each case has to be worked out by itself. Often the patients themselves can determine their optimum mode of living, not only from the viewpoint of comfort, but also from that of earning a livelihood.

**CASE 4.** A E, an 82-year-old man, was seen in February, 1937, with cardiovascular limitation, both in the form of angina pectoris, helped at first by nitroglycerin and in the form of congestive failure, which was greatly helped by digitalis. The patient suffered from progressive loss of vision, which began in 1910 and resulted in practically complete blindness in 1922, when glaucoma manifested itself; he continued to be active thereafter, however. In 1924, an electrocardiogram showed intraventricular block. The blood pressure was 170/110. The patient had dyspnea when he hurried, but his blindness prevented him from walking fast enough to cause much trouble with the circulation. In 1925 he developed angina pectoris and the diagnosis of hypertensive heart disease was added to the previous ones. In 1926, definite evidence of

congestive heart failure appeared, and the patient felt better when digitalis therapy was instituted. In 1927, he was given hypertonic salt solution intravenously, and this procedure was followed by an attack of coronary thrombosis. In the 10-year period following this attack, he suffered a good deal of cardiovascular limitation caused by angina pectoris, which was relieved by nitroglycerin, and by congestive failure, which was helped very much by digitalis.

The patient gradually learned how to improve his health by rest breathing exercises and a careful diet. By this regime, his symptoms largely subsided in the course of years, so that he had almost no angina pectoris and little or no dyspnea although it is true that he walked very slowly. He continued actively at work throughout the years, going to his office daily and resting almost completely in bed over week ends. On one occasion in the fall of 1937, he was referred to the Baker Memorial Hospital for rest on account of an increase in coronary insufficiency; this treatment resulted in considerable improvement. In February, 1940, he contracted bronchopneumonia and was admitted to the hospital. Although he seemed to weather the infection, he became very weak and died from a fresh coronary thrombosis 10 days after entry.

**Autopsy.** The heart weighed 500 gm. There was a mural thrombus in the left ventricle, with acute coronary thrombosis in the left descending branch, as well as a healed cardiac infarction, generalized atherosclerosis and marked coronary sclerosis.

Here was an ingenious and wise man who taught his doctors how Nature, common sense, the affliction of blindness and personal experimenting aided longevity while he continued a useful life.

**CASE 5.** M P, a 43-year-old salesman, underwent a total thyroidectomy in January, 1934, to relieve severe angina pectoris of 6 months duration. There was but little apparent improvement, and for the next 3 years the patient was unable to walk up a slight grade on account of chest pain. In view of a low basal metabolic rate ( $-32$  per cent) and some evidence of myxedema he took 1/10 gr. thyroid daily. For one year (1937-1938) he offered the information that his attacks were more marked after meals and dependent on the type of food ingested. After considerable experimenting with himself and with the lapse of time, he has been able finally to walk about 4 miles at a time without having an attack of angina pectoris, but he has learned to walk very slowly.

This patient's own comments on his well-being and freedom from attacks are interesting. Although the myxedema has had a quieting effect, he also has voluntarily slowed down, since his walking is methodical, never increasing the rate above 60 steps a minute. The evidence tends to show that a "slow pace in life" may allow a survival, at least in some cases.\*

\*In our case of coronary disease with severe angina pectoris treated successfully by total thyroidectomy in 1934, the interest is very much increased. A 47-year-old physician was treated by the same method without apparent benefit. After to total thyroidectomy he was completely relieved of his angina pectoris but he slowly developed myxedema. For this he took enough thyroid to hold his basal metabolic rate within normal limits. He felt well and despite adequate thyroid he has symptoms failed to suffer a recurrence of angina pectoris except when he pushed himself hard. He is still carrying on general practice at the age of seventy-three years. It is evident that he had a natural recovery of coronary sufficiency doubtless through the development of collateral circulation with a lowering of peripheral resistance—of a serious period of illness by the total thyroidectomy.

CASE 6. D.G., a 45-year-old jeweler was first seen medically in 1923. He had no complaint except that he had been rejected for life insurance on account of elevation of blood pressure, which was found to be 194/104. The patient was a dynamic person who enjoyed attending lodge meetings at least three or four times a week, and who took an active part in all the discussions. Although he was advised to "slow down," he refused to follow this advice, in view of the absence of symptoms.

The first attack of angina pectoris occurred in 1929, but in spite of this warning, the patient did not change his mode of living. Although he had no further attacks until 1934, the electrocardiographic tracings during the later years showed evidence of coronary-artery disease with myocardial involvement in the form of progressive changes in the T waves of Lead I. The attack in 1934 lasted 2 hours and required morphine for relief, but was not convincing enough to cause a change in the patient's habits. However, a second attack of coronary occlusion accompanied by paroxysmal auricular fibrillation in July, 1935, completely changed his idea of how to live and be happy.

Five years have elapsed since the severe attack of coronary occlusion, and during this period the patient has resorted to the use of nitroglycerin on the average of about once in 2 weeks, when he finds himself driving his automobile in difficult traffic (this is not a safe thing for him to do). The physical findings during this 5-year period have not changed. The blood pressure has remained around 200/110. Recently the vital capacity was 2400 cc., and there was no evidence of failure. Treatment has consisted of 5 gr. of quinidine sulfate twice daily, 1½ gr. of aminophylline three times daily, and 10 minims of Lugol's solution once daily.

Since the attack in 1935, the patient has adopted a strictly followed routine. He arises at 7 a.m., gets his own breakfast and walks about ½ mile to the bus very slowly (he says, "I have plenty of time and never rush for an oncoming bus, for there will be another right along"). Up to January, 1940, he took rest periods in the afternoon for about 45 minutes or 1 hour; since then he has felt so well that he has given them up. He works until 5:30 or 6:00. His meals are light, with dinner at 6:30. Although he retires at 7:30, he reads much of the night or until he is drowsy. Once or twice a week he spends an evening at either a lodge meeting or visiting friends, but at all times returns home not later than 10:30. He never goes out on Sunday. Although his production, per working hour, has decreased, he has been able to meet his financial obligations and has maintained a living income.

Here is another example of what careful living, in addition to a natural tendency to longevity, can do.

CASE 7. M.B., a 48-year-old schoolteacher, consulted us on June 12, 1926, because of the recent onset of tachycardia and dyspnea. On physical examination, she showed moderate cardiac enlargement, with a well-marked, rolling, mid-diastolic murmur at the apex, accentuation of the first apical sound and of the pulmonic second sound and an apical third sound. The heart rate at the apex was 160, at the wrist 104. The electrocardiogram showed auricular fibrillation with slight right-axis deviation. A high degree of mitral stenosis was clearly evident.

Digitalization was begun and maintained thereafter. For 14 years, the patient has continued to teach, with occasional short pauses caused by acute illnesses or to re-

cover from fatigue. Now, at the age of 62, she is ready to retire after a long, useful service. Despite increasing symptoms of pulmonary congestion and slight heart failure in the last 10 years, she has kept at work by the most careful regulation of her daily life. Her only activity has been to go to school, aside from brief vacation trips to the South in the winter or spring. She has rested during her long summer vacations. Often she has remained absolutely at rest after leaving school on Friday afternoon until she has gone again on Monday morning. She has survived several attacks of pulmonary infarction and of pneumonia and colds of lesser severity. For years she was able to drive her car but did very little walking. Only once or twice has she needed diuretic therapy, rest therapy and digitalis being adequate to prevent or control congestive failure.

When examined on June 15, 1940, the patient was in fairly good condition; she was convalescent from an illness of 7 weeks, probably precipitated by a small pulmonary embolism. She showed no evidence of heart failure. The heart rate was 56, and the rhythm irregular. The blood pressure was normal. The heart was large, with a loud systolic and a slight mid-diastolic murmur at the apex.

This case of rheumatic heart disease of more than average severity has permitted not only a considerable longevity but also a useful life of teaching through the carrying out of a sensible mode of life and the good fortune in being able to maintain a fair state of health and to avoid severe rheumatic infection. Familial longevity doubtless has entered into the picture.

#### DISCUSSION

Although this group of patients is small, it does represent a considerable number of cases of a similar character that physicians encounter during many years of experience. Often, however, the consultant may be unaware of the final outcome, nor does he always know what progress the patient has made subsequent to the consultation. It is important to recognize that the prognosis is as likely to be favorable as unfavorable in the majority of cases.

Three of the 7 cases reported showed serious heart trouble at the outset, with an unfavorable or even a grave prognosis; nevertheless, the patients experienced a natural or spontaneous recovery and did very well for a good many years. One of these patients was fortunate enough to have had an acute infection that saved him from a needless valvotomy, with a possibly fatal outcome.

In the second group were 4 patients, 3 of whom were able to continue to earn a livelihood for many years in spite of serious heart disease. This was accomplished undoubtedly by the careful program that each one mapped out for himself. The fourth patient, although he was unable to return to his original occupation, could without question employ himself in a less vigorous trade than that of a traveling salesman.

## SUMMARY

We have presented 7 cases of severe heart disease in which the patients, who at the onset of their illness appeared to have unfavorable prognoses, but through natural recovery or sensible living, were able to lead long and useful lives. This group emphasizes the statement that in acute heart disease "functional recovery may be so complete that the ultimate prognosis is good for many years

after." It is not to be inferred, however, that medical attention can be dispensed with. Furthermore, every person should seek medical counsel at the onset of symptoms, whether or not they are of cardiac origin.

## THE TREATMENT OF HAND INJURIES\*

SUMNER L. KOCH, M.D.†

CHICAGO

THE basic surgical principles involved in the treatment of compound injuries are nowhere better exemplified than in the painstaking and purposeful treatment of injuries of the hand.

Treatment that ensures arrest of bleeding and protects the open wound from further contamination constitutes ideal first-aid care. Most cases require only the immediate application of a sterile dressing, held in place with the moderate pressure of a snug bandage and in severe cases reinforced with a light splint. The more promptly such a dressing can be applied, the less is the danger of contamination of the open wound with virulent organisms. With increasing experience, surgeons have come to realize that the most important potential sources of such organisms are the uncovered mouths and noses of excited and voluble bystanders, or of any persons who may be attempting to apply some form of emergency treatment without first masking their faces. In most cases of compound injury, uncovered hands, unmasked faces and instruments hastily sterilized by rinsing them in some antiseptic solution carry a greater menace for the patient than the instrument that caused the wound or the bacteria that may have been present on the patient's skin at the time of injury.

A second principle, sometimes forgotten until too late, is that diagnosis should always precede treatment. Every surgeon of experience knows how little information can be obtained by inspection or probing of an open wound. The hasty operator may forget that accurate and important information can be quickly obtained by examination of the function of the part below the site of injury. Division of the ulnar or median nerve,

for example, or of the flexor tendons of thumb and fingers can be recognized with certainty by simple tests that every first-year medical student knows full well and that too many residents and house officers have forgotten.

Once the extent of the injury has been determined, the next question is to decide what should be done immediately. Should cleansing of the wound be followed by operative repair of the injured structures, or should such repair be deferred until the question of wound infection can be answered with certainty? The time that has elapsed, the place where the injury was sustained, the first-aid treatment, the character of the injury itself and the facilities available for repair all come into consideration. Rarely would one attempt operative repair of an extensive wound if more than two hours had elapsed. Wounds sustained out of doors, in an automobile accident or in the street are likelier to be seriously contaminated than those sustained in a clean factory, a workroom or a kitchen. Careless or unthinking first-aid treatment may permit secondary wound contamination that leads to serious infection. Crushing injuries and deep and extensive lacerations are more difficult to transform into clean surgical wounds than clean cut incised wounds caused by glass or sharp metal. The attempt to repair a serious injury in an emergency or a ward dressing room without adequate assistance is almost certain to result in disaster. Difficult surgical procedures demand every advantage that a well-equipped operating room and expert assistants can provide.

Whether or not operative repair of injured tissues is to be undertaken immediately, every wound should be carefully and thoroughly cleansed at the earliest possible moment to convert the contaminated wound into a clean wound. To secure

this result, I know of no more effective method than patient and thorough cleansing with ordinary white soap and sterile water, applied with soft sterile cotton and hands covered with sterile gloves, under eyes that are alert and mouth and nose that are completely masked (Fig. 1). Soap-and-water cleansing of at least ten minutes' duration is followed by thorough and prolonged irrigation of the open wound and all its recesses with warm physiologic saline solution. Charity may cover a multitude of sins, but the hope that

an open mind for the best method of meeting the problems in question. That there must be one most effective technic in treating open wounds in spite of the widely divergent methods and ideas in vogue whenever compound injuries are treated, no one would deny. Tomorrow may bring improved methods, but the immediate problem is to accomplish the best possible results with the facilities available today.

Briefly, then, the treatment of patients with hand injuries should include the following: gen-

FIGURE 1. *Preparation of the Field of Operation.*

*A—a small table, with two basins of sterile water, a pile of soft cotton, a cake of plain white soap, a towel and dry sterile gloves, is ready beside the operating table. B—the cleansing of the field of operation is gentle, but thorough and painstaking, and is continued for at least ten minutes (Koch<sup>1</sup>, reproduced by permission of the publisher).*

sulfanilamide crystals can cover a multitude of virulent organisms, which may have come from the open mouth or uncovered nose of well-intentioned persons giving first aid, and completely neutralize their harmful effect is certain to result in disappointment. The value of chemotherapy should not be minimized, but the relative importance of the ounce of prevention and the pound of cure is just as great in wounds of the hand as in any potential disaster.

Time and space do not permit the discussion of many details that are essential in actual surgical treatment, or of the basis on which conclusions that may seem too dogmatic are founded. Nevertheless these conclusions are based on a considerable experience and a constant search with

eral anesthesia in cases of severe injury; a bloodless field secured with the aid of a blood-pressure cuff inflated to 250 mm. of mercury; incisions that permit adequate exposure of injured tissues, retracted muscles and tendons and that do not cut across flexion creases (Fig. 2); gentle handling of tissues, no matter how much greater the expenditure of time; accurate hemostasis; the use of silk ligatures and sutures of the finest caliber that afford the required tensile strength; reduction of fractured bones without interposition of foreign material; repair of divided tendons by a method that leaves the tendon ends as free as possible from the irritating action of foreign material; suture of divided nerves with the finest possible silk suture that includes in its

bite only the epineurium (Fig. 3); and, finally, complete and accurate wound closure without drainage. These details of treatment are carried

FIGURE 2. Lines of Incision.

Incisions for securing adequate exposure should be made to be parallel with flexion creases and not across them. Median incisions of the fingers and forearm and cruciate incisions should always be avoided (Koch<sup>1</sup>; reproduced by permission of the publisher).

out not in blind adherence to a routine inherited from the past, but as the result of a serious effort to learn by experiment, by observation of one's

Perhaps no one of these details is likelier to arouse controversy than the suggestion to close the wound accurately and without drainage; yet it is just as vital to secure healing by primary union for the patient who has sustained a division of nerves and tendons as it is for the patient whose hernia has been repaired or whose stomach has been anastomosed to the small bowel. It is even

FIGURE 3. Technic of Tendon Suture (Mason).

Both methods (a and b, and c and d) are consistent with the important criterion that the free ends of the two segments be as free as possible from foreign material. Experimental studies indicate that in the second method (c and d) there is less tendency for the tension suture to cut through the tendon and permit partial separation of the sutured ends (Koch<sup>1</sup>; reproduced by permission of the publisher).

more important, since any wound infection, no matter how trivial, impairs the usefulness of structures, such as tendons and joints, the function of

own results and those of others and by thoughtful consideration of what methods afford the best possibility of securing the desired result of healing with a minimum loss of time and function.

which depends on complete freedom of movement. I should even say that if the wound cannot be closed accurately and without tension because of loss or destruction of covering tissue, it

is the obligation of the surgeon to provide covering tissue by the use of a flap or graft, so that

demand immediate attention, but to miss the most favorable opportunity to secure closure of a wound

FIGURE 5. *Crushing Injury of the Hand Treated by Immediate Soap-and-Water Cleansing, Wound Repair and Immediate Covering of the Extensive Raw Surfaces with Grafts of Intermediate Thickness (patient of Dr. Michael Mason). Appearance of hand at the primary dressing.*

the desired result of immediate wound closure can be attained (Figs. 4, 5 and 6). If the use of a

with the aid of a graft or a flap where there has been extensive loss of covering tissue and to await

FIGURE 6. *Crushing Injury of the Hand Treated by Immediate Soap-and-Water Cleansing, Wound Repair and Immediate Covering of the Extensive Raw Surfaces with Grafts of Intermediate Thickness (patient of Dr. Michael Mason).*

*Hand immobilized with aluminum splint and enveloped in a large gauze dressing, bandaged under moderate pressure, and left undisturbed for fourteen days after operation.*

flap or graft is necessary, one rarely undertakes repair of divided nerves or tendons until wound healing is complete. The latter procedures do not

the formation of granulation tissue and the crippling fibrosis invariably associated with it before attempting to secure wound closure are misfor-

tunes for both the surgeon and the patient

When the wound has been closed, whether by suture or graft, a large pressure dressing consisting of fluffed gauze, cotton waste or sea sponges is applied over the entire wound area, and the part immobilized with the aid of a light aluminum splint. Inflamed and injured tissues need rest, and the rest secured by the compression bandage and splint is uninterrupted, if possible, until the time when the sutures should be removed. If the treatment has been painstaking and well performed, one may wisely leave the dressing and wound untouched. The patient is watched carefully for evidence of impaired circulation and wound infection; the dressing is left undisturbed.

Finally, one cannot refrain from emphasizing

the oft-repeated precept. The outcome of any case depends primarily on the surgeon who first sees the patient. If his treatment is skillful and well considered, rarely will anything more need to be done at a later date, and if further treatment is necessary the conditions will usually be favorable. If the treatment rendered immediately after the injury is haphazard and thoughtless, it too often happens that no surgical care, no matter how skillful or painstaking, can compensate for the initial neglect of the basic principles of treatment of compound injuries.

## MEDICAL PROGRESS

### KIDNEY DISEASE

REGINALD FITZ, MD\*

BOSTON

SINCE my last review,<sup>1</sup> the varying problems of Bright's disease have continued to be attacked in many ways: by clinicians who have attempted to observe patients at the bedside more accurately than heretofore; by laboratory workers who have devised ingenious experiments to produce, prevent or cure experimental nephritis, and even by surgeons who have tackled the lesions of nephritis by surgery rather than by more orthodox medical methods. Hence any reader in this general field of medical literature soon has his appetite surfeited. To avoid mental indigestion, he is driven, perforce, to include in his diet only those literary delicacies that seem most digestible for his particular type of mind. This year, therefore, I have made no attempt to summarize all the communications of the last twelve months but instead have selected for discussion a group of papers that I have found both readable and stimulating.

One of the ideas that nowadays attract almost every clinician is the thought of being able to use plasma in some form for purposes of blood transfusion. The possibility of utilizing concentrated plasma protein solutions in the management of renal edema associated with reversed albumin globulin ratios and lowered blood protein concentrations springs naturally to mind. Thus the ob-

servations of Aldrich and Boyle<sup>2</sup> are important as being among the earliest on record in this particular effort. These workers used concentrated solutions of serum protein as a diuretic in a group of patients with nephrosis. They dehydrated pooled serum to make its normal protein concentration four times normal, and injected the resultant solution by vein in doses that varied from 25 to 65 cc. In most of their cases, diuresis followed such treatment and continued until the edema was eliminated. The possibilities of developing this method of therapy in certain types of renal edema are promising. Concentrated plasma, in fact, may prove to be an excellent diuretic not only in renal edema but also in other conditions in which water retention depends on disturbed physicochemical relations in the blood and tissues.

A few years ago a charming doctor from Dublin named O'Shaughnessy visited this country. He spoke in New England at several of our local medical meetings—a fiery, enthusiastic young Irishman, sincerely interested in the possible value of omentopexy for the treatment of angina pectoris. His idea was to bring a piece of omentum through the diaphragm, attach it to the heart apex and thereby stimulate the formation of a new blood supply to the myocardium. His work did not stir up great excitement in Boston, but everyone who heard O'Shaughnessy speak was impressed by his sincerity and uprightness. The announcement of

All articles in this series will be published in book form the current volume is *Medical Progress Annual 1940* (Springfield Illinois: Charles C. Thomas Company 1941) \$4.00.

\*Assistant to the dean and lecturer on the history of medicine, Harvard Medical School.

his death on active service with the British Expeditionary Force in Flanders made all his American friends feel badly, for no one could meet him without hoping to see him again. But at least his ideas carry on. MacNider and Donnelly,<sup>3</sup> modifying his method, have attempted to establish in animals an adventitious circulation in the kidney by omentorenopexy, and Weeks, Steiner, Mansfield and Victor<sup>4</sup> appear to have successfully treated experimental renal hypertension by the operation of splenorenopexy. By the last procedure, it seems, collateral circulation between the splenic sinusoids and the capillaries about the renal tubules was provided, with an improved circulation through the kidneys and a resultant fall in blood pressure. When the fused spleen and kidney was later removed, the blood pressure soon returned to its previous level of hypertension. Perhaps eventually we shall hear more of the clinical usefulness of O'Shaughnessy's ideas and of their application in directions other than he supposed.

Goldblatt's work continues to inspire clinicians to hunt carefully for patients with hypertension whose abnormal blood pressure level is caused by unilateral renal conditions. A variety of new cases have been reported: perhaps the most peculiar one is that described by Koons and Ruch,<sup>5</sup> which concerns a seven-year-old child with a Wilms's tumor complicated by hypertension. The tumor did not appear to be the source of the hypertension since, when an exploratory operation was performed, extensive metastases were seen and felt, and these presumably would have perpetuated hypertension after nephrectomy if the tumor had manufactured any pressor substance. Yet actually the hypertension disappeared when the kidney and the primary tumor were taken out. Koons and Ruch explain this happening on the assumption that, since the tumor practically surrounded the kidney, it caused renal ischemia and acted in much the same way as the cellophane membrane that Page and his associates<sup>6</sup> placed around the kidney in animals to produce experimental hypertension. If this explanation is correct, this is the first clinical confirmation on record that Nature has a means of duplicating in man so bizarre a renal lesion as the one made synthetically by Page in the laboratory.

Many typical cases of unilateral atrophic pyelonephritis cured temporarily, at least, of hypertension by nephrectomy are now on record, so that an increasingly large group of such patients are being followed for lengthening periods. A patient of mine,<sup>7</sup> whose case was reported in 1940, continues to have normal blood pressure; to the list have been added during the past year a Cana-

dian case reported by Patch, Rhea and Codnere<sup>8</sup> and 5 new cases reported by Barker and Walters,<sup>9</sup> of the Mayo Clinic. Everyone seeing these cases maintains a proper attitude of conservatism over end results. Palmer, Chute, Crone and Castleman<sup>10</sup> express the generally accepted viewpoint: for success in this operative approach to hypertension, only those cases must be selected for surgery in which there is no recurring pyelitis or other abnormality on the apparently normal side.

Neurosurgeons have become a little less vociferous than they have been in previous years. To be sure, Peet, Woods and Braden,<sup>11</sup> staunch proponents of such complicated operations as bilateral supradiaphragmatic splanchnectomy with lower dorsal sympathetic ganglionectomy, have reported results in 350 cases. They claim that in slightly over half the cases in their series there was significant reduction in blood pressure and that after operation, clinically speaking, their patients' disability was improved in the vast majority of cases. This is a good record, which speaks for itself. On the other hand, Davis and Barker,<sup>12</sup> of the thiocyanate school, claim that bilateral splanchnic section fails to give relief to patients who cannot obtain equal benefit from the proper use of this drug. They still maintain that many patients with hypertension respond favorably to thiocyanate and that the drug is not unduly dangerous, and apparently, they continue to use it with satisfaction. The perfect treatment of hypertension is still undiscovered.

When the American College of Physicians met in Boston this spring, no single paper was read that provoked more discussion in the corridors, bedrooms and dining rooms of the Hotel Statler than that of Page and his associates<sup>6</sup> on the use of kidney extract in the treatment of experimental and clinical hypertension. Beforehand, everyone wondered how Page would describe his most recent work, and afterward, how convincing were the results reported.

Page has elaborated a theory that is interesting. He believes that the diseased kidney may produce a substance which raises blood pressure and that this, in turn, can be neutralized and rendered inert by an antistubstance developed in the normal kidney. With this thought in mind, he at first carried out experiments on animals in which extracts from normal kidneys were used in an attempt to counteract experimentally produced hypertension. Elevated blood pressure was induced by several different means and appeared controllable by properly graduated doses of normal renal extracts. These results were sufficiently convincing to Page to make him try the next

hurdle At the meeting of the College of Physicians, he reported on 19 human cases of hypertension treated in similar fashion He drew no conclusions that were at all unguarded However, he produced evidence to suggest that the prenteral injection of renal extract in his cases appeared, on the whole, to have been of some value in treatment In certain cases, for example, there was marked improvement in the condition of the eye grounds, in the cardiac symptoms and in the blood pressure levels On the other hand, severe reactions occasionally developed, owing, he believes, to the protein content of the extracts employed He concluded his remarks, wisely and sanely, by stating that the use of kidney extracts in the treatment of certain cases of hypertension probably has some merit and at least deserves further study Knowledge concerning the true usefulness of the technic or even of the idea behind it is too fragmentary to bear much discussion Yet no one who heard Page speak could fail to believe that his work deserves watching

When one leaves the laboratory and turns more closely to the bedside for the basis of his reading, he encounters several worthwhile papers Lupus erythematosus is much in the public eye at the moment Hence the paper by Suckney and Keith<sup>12</sup> is interesting They studied the kidneys in 15 fatal cases and concluded that there is no distinct renal lesion peculiar to the disorder In 8 of their cases, the kidneys appeared normal, in 2, glomerulonephritis was found, and in 5, there was no more specific form of nephritis than a certain amount of proliferation of the glomerular endothelium, together with irregularity and thickening of its basement membrane Thus lupus erythematosus cannot be regarded as having any typical form of kidney lesion attached to its pleomorphic pathology

The relation of tonsillar infection to nephritis has been discussed perennially for a long time Illingworth,<sup>14</sup> in England, is the latest clinician to claim that tonsillectomy neither cures nephritis nor prevents its progress, in fact he even goes so far as to suspect that tonsillectomy may predispose to nephritis or may actually precipitate an attack The paper was printed a year and a half ago, and his ideas seem not to have been repudiated or generally supported by his British colleagues

Acute nephritis and the acute exacerbations that so often occur in the course of chronic nephritis have also received due consideration Hayman and Martin,<sup>15</sup> in an excellent paper, have analyzed the histories of 22 cases of acute nephritis The

most interesting point in their paper is that about two thirds of their patients recovered completely. Acute nephritis, too, as they point out, is, on the whole, a disease of young people and, contrary to Illingworth's views, is likely to be precipitated by acute upper respiratory tract infections involving the throat, sinuses and ears

That acute glomerulonephritis may follow so simple a skin infection as impetigo is emphasized in a paper by Fletcher<sup>16</sup> He picked out of the Johns Hopkins Hospital Clinic 11 cases in which glomerulonephritis followed impetigo or some other superficial skin infection, although, to be sure, beta hemolytic streptococci were not infrequently found in these cases on throat as well as on skin culture That skin infections may be followed by so serious a complication as glomerulonephritis in certain cases is worth remembering

Seegal, Lytle, Loeb, Jost and Davis<sup>17</sup> have re-emphasized the relapsing character of chronic nephritis They say that the life history of a patient with chronic nephritis is often punctuated by repeated attacks of acute nephritis superimposed on the basic underlying chronic lesion Such attacks are usually accompanied by transient decreases in renal function or by sudden marked hematuria One of their patients with chronic nephritis had, they believe, several attacks of acute nephritis in the course of a few years This paper is an interesting attempt to establish the complete picture of chronic nephritis through utilization of the method of careful follow up studies on a small group of patients observed over a long period To my mind their ideas carry considerable weight It is highly probable that repeated acute insults, each with or without complete healing, do much to account for the characteristically slow progress of many cases of chronic Bright's disease

Now that the ordinary clinician is becoming educated to recognize gout more readily than he used to, gouty nephritis is again receiving attention Talbot and his co-workers<sup>18</sup> at the Massachusetts General Hospital have written a clever paper to remind us of what our English forbears knew so well that most subjects with gout show some evidence of renal damage Certainly they have performed some painstaking and superb studies on earmarking the characteristic renal lesion of gout—clinical studies that would have amazed old worthies like William Cadogan or Benjamin Franklin, who thought they understood the gouty diathesis The urates seemingly can be filtered through the gouty kidney but are reabsorbed with difficulty Drugs like cinchophen and Salycan depress further urate resorption but stimulate urate clearance, colchicine, stringently

enough, has no particular effect one way or the other, so that at present why it appears to behave so beneficially in gout is uncertain.

The sulfonamides are so popular that naturally they have been used abundantly in the treatment of various urinary infections. Cook<sup>19</sup> has written a helpful paper describing which ones of the new members of the family are of particular help in combating genitourinary infections caused by a variety of different organisms. It is obvious that the causative agent must be established and that each case is best treated individually. In Cook's experience, sulfanilamide, dimethyldisulfanilamide and sulfanilylsulfanilamide were most effective against gram-negative bacilli, beta-hemolytic streptococci and the proteus bacillus, whereas sulfapyridine seemed more useful to combat staphylococcal infections. Sulfathiazole proved useful against gram-negative bacilli and staphylococci but was not very efficacious against beta-hemolytic streptococci. Finally, when the renal function was poor, azosulfamide seemed to be the drug of choice since it appeared to have little or no injurious effects on the kidney. In this connection it is worth remembering that all members of this family, even when properly used, may bother the renal system. The sulfonamides tend to precipitate in the collecting tubules or even in the ureters and bladder unless due care is taken, and thus they act as renal irritants. I like Arnett's<sup>20</sup> rule in using these drugs—a minimal intake of 3000 cc. of fluid each day, with an output of 1500 cc. or more, and careful watching of the urine for the presence of hematuria. No patient enjoys having to put up with urologic manipulation to rid himself of the chemical calculi that may form when he uses these medicines.

\* \* \*

On the whole, the past year has been one of activity in the advancement of knowledge regard-

ing Bright's disease and its treatment. The trend of the times is to pay increasing attention to renal physiology, so that a great deal of work is now going on with pressor substances and their relation to hypertension. On the other hand, clinicians still continue to see cases of chronic nephritis frequently and to hope for the development of more secure methods for the cure and prevention of this disease than now exist.

## CASE 27291

## PRESENTATION OF CASE

A seventy-two-year-old man entered the hospital for study.

The patient was seen for the first time by a staff member of this hospital nine years before admission, when diagnoses were made of irritable heart,—possibly on the basis of coronary disease,—auricular fibrillation and myxedema. Shortly afterward, he was confined to bed for twelve weeks, suffering from what was either pulmonary infarction or an incidental pulmonary infection. Seven years before admission, he had an attack of dyspnea, which lasted fifteen minutes and was not accompanied by pain, palpitation or cough. He remained in bed for three days, after which he returned to his usual activities. Apart from occasional shortness of breath, he remained well for the next seven years, and during the summer preceding his admission he played golf without untoward effect. Four months before entry, the patient suffered a violent nosebleed, and a month later noticed the onset of gradually increasing dyspnea, even while walking on level ground. A severe attack of dyspnea developed during a walk ten days before admission; it lasted ten minutes and, again, was not accompanied by other symptoms.

The patient had been constipated for some time and had noticed an urgency and frequency of urination, with the passage of small amounts, and a nocturia of three times a night. Several days before entry, a dry cough had developed.

When thirty-two years old, the patient had suffered from mumps complicated by severe bilateral orchitis. Shortly after this episode, he noted marked loss in sexual power, which proceeded to complete impotency. His skin became fine in texture, his beard regressed, the pubic and axillary hair fell out, and his phallus decreased in size. There was no marked loss of strength or of weight. He did not experience hot flashes at any time. It was thought by some that the pitch of his voice became higher.

He had four children, who were living and well.

On physical examination, the patient's features were definitely eunuchoid in appearance; it also

had somewhat the appearance of that seen in myxedema. The skin as a whole was of fine texture, the speech was slow, and the hair of the head was normal but that of the extremities, axillas, pubic region and perianal region was absent; the testes were small, no prostate tissue could be felt.

The neck veins were moderately distended, with visible pulsations. The left border of the heart was 3 cm. outside the mid clavicular line,—the heart was appreciably larger than it had been nine years previously,—and a soft systolic murmur was heard at the apex and to the left of the sternum. The aortic second sound was greater than the pulmonic. The rhythm was irregular, the blood pressure 160 systolic, 90 diastolic. A few rales were present at the right lung base. The abdomen was normal. There was a minimal pitting edema of the shins.

The temperature was 98°F, the pulse 88, and the respirations 20.

The urine showed a + test for albumin. The blood showed a red cell count of 4,520,000 with a hemoglobin of 13.4 gm (photoelectric-cell technique), and a white cell count of 8400. The blood sugar was 82 mg and the cholesterol 101 mg per 100 cc. The 17-ketosteroid excretion in the urine was very low, but not absent, on two occasions, the actual figures were 1.4 and 1.2 mg per twenty-four hours. There was no excess of follicle stimulating hormone in the urine, the basal metabolic rate was -15 per cent.

An x-ray film of the chest showed the diaphragm to be high on the right side and its respiratory movements limited. There was mottled dullness along the right border of the heart, and in the angle between the heart and diaphragm; the costophrenic sinus on the right side was shallow. The heart shadow was considerably enlarged in its transverse diameter, and there was a definite bulge of the right auricle. The supracardiac shadow was not increased, the appearance of the aorta was not remarkable, and there was no visible calcification or mediastinal masses. X-ray examination of the skull showed the sella turcica to be rather large and bridged, but no abnormalities of shape or erosion of the clinoid processes could be seen. The pineal gland was visible and in the usual position. The bones of the skull were unusually heavy. There was no evidence of increased intracranial pressure, and the usual blood-vessel markings were present.

The electrocardiogram showed an unusual ectopic auricular rhythm, regular at 160 or more; this was considered to represent an ectopic auricular tachycardia. For the most part, there was a

2:1 ventricular response, with an occasional ectopic ventricular contraction. The ventricular rate was 85;  $T_1$  was low,  $T_2$  slightly inverted,  $T_3$  inverted.  $Q_3$ , which varied from 2 to 3 mm. in length, was inverted,  $R_4$  upright, and  $T_4$  low.

The patient was given digitalis; the heart slowed but remained irregular, with a varying degree of auriculoventricular heart block. The edema had cleared on the fourth hospital day. Ten days after admission, the patient was started on testosterone propionate, 12.5 mg. intramuscularly three times weekly. This therapy was continued until three days before death. At two weeks, a chest plate showed that the process in the lungs had cleared; the diaphragm was in the usual position, and the lung fields were clear; the heart shadow was roughly triangular and was increased somewhat in size, the increase being largely to the right.

The patient was discharged under the care of his physician.

He made a follow-up visit two months after discharge. At that time, everything seemed to be going very well. He felt considerably stronger; he had noted a return of sexual power.

At 4:00 in the morning after the follow-up visit, the patient's wife was awakened by nightmarish noises from her husband. She failed to arouse him and finally called his physician, who arrived at 5:30 a.m. The patient was in moderately profound coma, with Cheyne-Stokes breathing and pinpoint pupils, but without obvious paralysis. The blood pressure was 200 systolic, 90 diastolic, and the pulse was 60. Three hours later, his condition was essentially unchanged, so that aminophyllin was administered, with the result that breathing improved and the patient roused to the point of movement and answered a few simple questions, although his words were scarcely intelligible. That evening, another administration of aminophyllin wrought no change; there was urinary incontinence, respiration had improved, the pulse was irregular at 80, the blood pressure was 185 systolic, 90 diastolic, and the pupils were constricted.

The following day, the patient was still semiconscious and incontinent, with Cheyne-Stokes breathing, a blood pressure of 150 systolic, 75 diastolic, and a pulse of 60. That evening, coma deepened, the temperature was  $102^{\circ}\text{F.}$ , the pulse was faster, and the patient seemed choked up.

The next day, the temperature was  $104^{\circ}\text{F.}$ , the respirations 50, and the pulse 100. Coma was even more profound, and diminished breath sounds and rales were heard throughout the right chest. The patient died that day.

## DIFFERENTIAL DIAGNOSIS

DR. EDWIN B. ASTWOOD:\* We have, in brief, a seventy-two-year-old man who, at the age of thirty-two, had a severe orchitis as a complication of mumps, followed by complete sexual impotency and certain other endocrine changes, but who remained well until nine years before entry, when he began to have symptoms referable to his heart. He finally entered the hospital for study, presumably because of increasing dyspnea and signs at that time of moderate cardiac decompensation. This cleared on digitalis and rest, and he was discharged well. He died suddenly, or at least died very shortly after a sudden attack, apparently of something entirely different. I do not believe that one single disease can explain everything. We might briefly discuss the three aspects that are most outstanding.

In the first place, the cardiac condition was longstanding, nine or ten years, and was accompanied by cardiac enlargement and finally by symptoms of failure, with the presenting symptom of dyspnea. I do not consider the mention of myxedema sufficient to account for the enlargement of the heart, or definite enough to account for the cardiac condition. The presence of dilatation of the right auricle, taken together with the ectopic auricular tachycardia, might indicate that there was myocardial damage in the right auricle. Auriculoventricular block also suggests myocardial damage, and in a man of seventy-two the most probable diagnosis is a coronary arteriosclerosis, with possibly myocardial infarction. I do not believe that the electrocardiograms are contradictory to such a diagnosis. When the patient entered the hospital, the physical signs were in keeping with an increased venous pressure, with pulmonary congestion and perhaps with pleural fluid and enlargement of the liver. This condition cleared on rest and digitalis, and probably represented a mild cardiac decompensation.

The cause of death, however, seems to have been a second type of condition. If the first assumption—that the patient had coronary arteriosclerosis—is correct, it is reasonable to assume that he had arteriosclerosis elsewhere, although no mention is made of it. He did have hypertension, and sudden coma coming on in a hypertensive man of seventy-two is suggestive of a cerebrovascular accident. The absence of localizing signs and paralysis indicates not a corticostriatal lesion, but perhaps a thalamic or mid-line lesion. A lesion in the pons might be more probable because of the pinpoint pupils and final hyper-

\*Assistant professor of pharmacotherapy, Harvard Medical School.

pyrexia. Whether the condition was thrombosis, embolus or hemorrhage rests on more details of the actual events leading up to the accident. This patient with complete impotency for forty years had a sudden restoration of sexual activity, and encountered an eventually fatal corn; this, I think, strongly suggests cerebral hemorrhage, possibly in the pons.

The third point to be considered is the nature of the endocrine disturbance. We are told in the history that the patient had mumps complicated by bilateral orchitis, and that this was the cause of loss of sexual power and loss of hair. There are several points that might be against such a concept. In the first place, it is very rare indeed for this type of orchitis to produce complete destruction of the testicular tissue. Experimentally, 2 per cent of viable testis tissue is sufficient to allow fairly normal endocrine function of the testis. Furthermore, complete azoospermia following such an orchitis is extremely rare, and still rarer would be complete destruction of the interstitial elements. Another thing against the possibility that the testicular atrophy was due to this cause is that the patient had complete impotency, which is scarcely credible even on the basis of complete castration. The loss of all body hair is something one does not usually associate with loss of testicular function. These three points are better explained by pituitary insufficiency, because all are symptoms of Simmonds's disease. This is not complete hypophyseal deficiency, however, because the patient maintained his weight and noted no loss in strength. There are a few other things that would support the concept of pituitary damage. The low metabolic rate, -15 per cent, and the myxedematous appearance, without real myxedema—the skin was soft and smooth, and the cholesterol value was 101 mg per 100 cc.—one would associate not with myxedema but with hypothyroidism of hypophyseal origin. The low 17 ketosteroids, as Dr. Albright has shown, could mean that he was an old and debilitated man suffering from some nonspecific illness associated with an absence or a great reduction of adrenocortical function and an absence of testicular function. All this endocrine disturbance may indicate a man of seventy-two who had no testis function, and the other endocrine changes may have been the result of old age. However, I should think that the major endocrine disturbance was hypopituitarism, and although I have never heard of such a sequela, the change apparently occurred at the time when he had mumps; it is possible that it might have been a complication of mumps, just like other glandular complications, or was perhaps related to meningitis.

In summary, I should consider the cardiac condition as coronary sclerosis, with infarction, the terminal event, cerebral hemorrhage, perhaps pontine, and the endocrine disturbance, hypopituitarism.

Dr J. H. MEANS: I saw this patient in consultation, and the question that was put up to me was as follows: "This patient has had myxedema for some time and appears to have a combination of myxedematous heart and coronary disease, with arrhythmia. Will you please see him and advise concerning treatment for hypothyroidism?" Because of his heart disease, they thought that they ought to go cautiously with thyroid. I saw him and did not think he had myxedema. I was impressed more than anything else with the factor of eunuchoidism. The man was emphatic in saying that this dated from the mumps. I was not certain whether anyone could get complete destruction of the testes from such an orchitis. I raised that, however, as one possible explanation, but also, like Dr. Astwood, suggested that it could be, and more probably was, on the basis of hypopituitarism.

One point about the diagnosis of myxedema: if this patient had had ordinary myxedema nine years before entry, and had not had treatment with thyroid in the interim, it would be impossible to have a picture of this sort. He would have been in an advanced stage of classic myxedema by the time of admission. The longest we have known any patient with myxedema to go is fifteen years—that is the utmost life expectancy. But after nine years with no appreciable change, we can say that he certainly did not have any ordinary myxedema.

One other point that should be brought up is whether the therapy in any way contributed to his demise. I suggested that it might benefit him, but I now believe that this may have been bad advice.

Dr FULLER ALBRIGHT: I went through the same reasoning as Dr. Astwood did and came to the same conclusion. I should emphasize one other bit of evidence, which Dr. Astwood did not make use of: there was no excess of follicle-stimulating hormone in the urine. If the patient had had complete destruction of his gonads by mumps and if there was no pituitary disease, he should have had a positive follicle-stimulating hormone test. The fact that it was negative is strong evidence that the pituitary gland was the origin of the disturbance.

The question has been raised about the rationale of administering testosterone in this case. It is our belief that testosterone has a much wider effect on the patient than merely to stimulate sec-

ondary sex characteristics. I refer especially to its effect on nitrogen metabolism, which consists in a marked sparing of protein. Unless there are some definite contraindications, I am inclined to believe that patients with lack of testosterone production should receive this hormone. Furthermore, we have found in patients with panhypopituitarism—that is, underfunction of all parts of the anterior portion of the pituitary gland—that testosterone has a markedly beneficial effect.

The question has also been raised whether testosterone therapy in any way led to the patient's death. One must probably proceed with caution in administering testosterone to elderly patients for fear that the increased libido might lead to excesses, which might be bad for their cardiovascular system. In this particular case, no such increase in libido resulted, and I think we can dismiss this possibility. Furthermore, the symptoms at the time of death do not convince me that the primary cause of death was coronary thrombosis.

One other possibility occurs to me. Patients with panhypopituitarism have a marked tendency to hypoglycemia. Testosterone therapy, by inhibiting the conversion of proteins into sugars, might easily increase this tendency. I should at least raise the question whether the beginning of the acute symptoms that led to his death was not hypoglycemia. The semicomatose condition in which he remained for two days is most suggestive of this condition.

#### CLINICAL DIAGNOSES

Coronary heart disease.  
Auricular tachycardia and fibrillation.  
Hypogonadism.

#### DR. ASTWOOD'S DIAGNOSES

Coronary sclerosis, with infarction.  
Cerebral hemorrhage, probably pontine.  
Hypopituitarism.

#### ANATOMICAL DIAGNOSES

Coronary sclerosis, with fresh thrombosis, left descending branch.  
Adenoma of the pituitary, neutrophilic type.  
Hypopituitarism.  
Atrophy of the thyroid gland.  
Atrophy of the testes.  
Chronic fibrous orchitis.  
Hypertrophy of the heart.  
Eunuchoidism.

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: The post-mortem examination showed obvious heart disease. The

heart weighed 560 gm. The patient had severe coronary sclerosis, and there was fresh thrombosis of the left descending branch, which had not as yet led to any gross infarction. On anatomic grounds, this was the only possible cause of death discovered, because in the brain there was no hemorrhage or evidence of thrombosis or cerebral softening. Of course, I cannot rule out hypoglycemia, and Dr. Albright makes out a strong case for it. The testes were a little small, evidently fibrosed. On microscopic examination, the left one appeared absolutely fibrotic. In our sections, we could not find a tubule or any sign of spermatogenesis. The right testicle was only three quarters destroyed; there were some persistent tubules and some mitotic figures among the spermatogonia. There was some effort at sperm formation, but it was incomplete and no sperm was present. I could not find any unmistakable interstitial cells in either testis. So that I think there is no doubt that there was extensive testicular destruction by mumps but, as one would expect, not complete destruction, and there must have been another reason for the marked depression in function of the remaining testicular tissue. The adrenal glands seemed a little small and the cortices possibly narrow, but histologically I could not see anything definitely abnormal. The thyroid gland was distinctly atrophied and weighed only 10 gm. Microscopically, the acini were small, and there was considerable increase in fibrous tissue. The pituitary gland was largely replaced by a neutrophilic, presumably nonfunctioning adenoma. Only a small rim of anterior lobe tissue persisted on one margin. It seems fairly evident that pituitary function was depressed because of compression by the tumor.

#### CASE 27292

#### PRESENTATION OF CASE

A fifty-seven-year-old housewife entered the hospital complaining of pain in her leg.

The patient had been known to have hypertension for about four years, with systolic blood-pressure readings reaching as high as 230. She felt well, however, until four hours before admission, when a smothering sensation developed under the upper sternum, without dyspnea, pain or cough. She lay down, and half an hour later a gradually increasing pain and tingling appeared in her left leg and was soon followed by numbness, cold and paralysis of this extremity. There was also transient tingling in the right foot. Her physician gave her morphine subcutaneously.

The patient had complained of frequent head-

aches and slight dyspnea on exertion for the previous month. There was no history of rheumatic fever, chills, night sweats, anginal pain or substernal oppression.

The patient's mother had died of "shock", one sister had hypertension.

On examination, the patient was pale and appeared anxious and acutely ill. The heart was enlarged to the left, with systolic and diastolic murmurs at the base, heard best over the aortic area. One examiner believed there might have been a mitral systolic murmur. The rhythm was regular. The blood pressure was 160 systolic, 110 diastolic. Occasional moist rales were heard throughout the chest. The abdomen was normal. The patient was unable to move her left leg, which was cold and a mottled pink below a definite line drawn horizontally through the lower margin of the vulva. In this leg no pulsations of the femoral, popliteal, posterior tibial and dorsalis pedis arteries were palpable, and the sphygmomanometer did not oscillate below the mid thigh or in the calf. Pulsations were present throughout the right leg.

The temperature was 99°F, the pulse 100, and the respirations 28.

An electrocardiogram showed normal P waves and QRS complexes in all four leads. The T waves were upright, but of low amplitude, the ST segments were very slightly depressed.

Two and a half hours after admission, the patient could move her left ankle, but not the toes. The leg was warmer, pulsations were palpable in the femoral artery to a point just below the profunda femoris branch, and the sphygmomanometer oscillated at the mid-thigh and calf, but not at the ankle.

Three hours after admission, an incision was made along the left femoral artery below Poupard's ligament under local anesthesia. Death occurred nine hours after admission.

#### DIFFERENTIAL DIAGNOSIS

DR CLAUDE E. WELCH: This is a short story, and it might be just as well to list first the few diagnoses that might be considered. These are peripheral embolus, a coronary attack, with marked spasm in the extremity, and a dissecting aneurysm of the aorta. Several points are of considerable importance in making the diagnosis. Of course, it is quite obvious as one reads the history that the clinical diagnosis was an embolus in the left leg.

I shall consider some features not consistent with that diagnosis. In the first place, the patient had had a hypertension for many years, but

four hours before admission a smothering sensation in the chest developed. This is a very important symptom, it seems to me, because the patient remembered it well enough to tell about it. It could have been due either to dissecting aneurysm or to coronary thrombosis. It is of interest that we recently had under treatment a man with acute coronary thrombosis whose initial symptom was pain in the leg. This pain was so severe that it was not until several hours later, after he had been given morphine, that he recognized that he had pain in the chest. The pain in the leg turned out to be due to spasm, and it was later proved that he had an acute coronary thrombosis. A smothering sensation is not at all typical of embolus.

There is nothing in the past history of any interest.

Clinical examination of the heart would mean something to Dr. Blard, but it does not mean much to me. The electrocardiograms are of some interest because the T waves were upright. All I know about electrocardiograms is that with coronary disease the T waves are often inverted. This electrocardiogram therefore offers a little evidence against coronary disease. At the onset the findings in the leg were typical of occlusion at the level of the bifurcation of the iliac artery. Apparently, the patient's pulsations returned, in part, while she was on the ward. That would lead the surgeon to believe that the embolus had descended to a spot where it might be accessible.

Apparently operation was performed; at least the patient was explored for an embolus and died nine hours after admission.

If the symptoms had been due to embolus, there was no reason to expect death at this time. Patients die usually of an unrelated cause,—coronary thrombosis or gangrene,—days or even weeks later, so that death at that time is not consistent with the single diagnosis of embolus. It seems to me, therefore, that many features in this case are inconsistent with the diagnosis of embolus, some are inconsistent with coronary thrombosis. There is nothing inconsistent with the diagnosis of dissecting aneurysm of the aorta, and that is the one that I make.

DR WILLIAM RICHARDSON: I should like to mention just one thing. I certainly agree with Dr. Welch, but I wonder if this is going to turn out to be the type of dissecting aneurysm that is due to media necrosis cystica, or whether syphilis may not actually have been present in this case.

I should like to ask Dr. Welch about spasm in connection with coronary disease. Is there a complete loss of pulsation?

DR. WELCH: In the case I mentioned, the patient had previously recognized vascular disease in the leg. There were no pulsations before or after the attack of coronary disease. We had another patient with absent pulsations immediately after an attack of coronary thrombosis; they returned after the acute phase had subsided.

DR. WILLIAM B. BREED: It seems obvious that the people who had charge of this patient did not think she had a dissecting aneurysm. They operated on the leg on the basis that she had an embolus. I am surprised that she did not have more pain in the chest, in the back and in the abdomen. Also, the fact that this happened rather suddenly makes me think that perhaps she did not have a dissecting aneurysm. I should favor an embolus, which was the diagnosis that the person who was in charge of her made.

DR. EDWARD F. BLAND: Is Dr. Welch disturbed by the diagnosis of dissecting aneurysm and by the finding of such good pulsations in the right leg in contrast with complete absence at first in the left, followed later by the appearance of pulsations in the upper portion of the affected leg? Do you often see that situation in dissecting aneurysm?

DR. WELCH: The peripheral circulation after dissecting aneurysms that go far down the aorta is very confusing. I am sure I have seen them follow a course like this in one or two cases. One has to assume a certain amount of spasm of the large vessels to account for the changing symptoms.

DR. BREED: The patient might perfectly well have died of a pulmonary embolus from the right side of the heart.

DR. BENJAMIN CASTLEMAN: That is very rare.

DR. BREED: Pulmonary emboli associated with coronary disease or occlusion are not at all uncommon.

DR. CASTLEMAN: The source of the emboli is very rarely from a mural thrombus overlying a right ventricular infarct. They may arise from an auricular thrombus associated with fibrillation or from the peripheral veins in the legs.

DR. RICHARDSON: I think the patient died of dissecting aneurysm, probably of pericardial tamponade.

DR. WELCH: Would it be amiss to ask Dr. Bland to interpret the cardiac situation for us?

DR. BLAND: The electrocardiogram is all right from the description. The diastolic murmur as described means aortic regurgitation. We do not know about the blood serologic findings, of course. An aortic diastolic murmur appears after dissection in a number of cases, probably because of

distortion of the aortic valve ring, owing to dissection backward toward the heart. If this murmur had not been present before and had appeared after the episode, it would be strong evidence in favor of dissection of the aorta.

DR. BREED: On the other hand, the electrocardiogram was taken only two hours after the onset of the disease, and you certainly could not rule out coronary disease or occlusion by an electrocardiogram taken at that time, could you?

DR. BLAND: No.

DR. CASTLEMAN: The surgeon is not here, but I shall read his operative note:

A careful re-examination of the extremity was made just before operation, to be sure that the signs were not improving as they had previously. The level of demarcation was the same,—just below the knee,—the foot was cold, the popliteal pulse was still absent, and the femoral pulsation was the same as previously.

A 10-cm. longitudinal incision was made under novocain, extending from Poupart's ligament downward over the course of the femoral artery. The artery was found to be pulsating throughout the entire extent of the exposure, which was for 4 cm. below the origin of the profunda femoris. The profunda itself was also pulsating, although all pulsations were definitely diminished. There was apparently some inflammatory reaction around the artery, since the femoral vein was quite adherent to it. The vein was dissected off and divided, and it was found that the upper end of the vein bled profusely, showing that there was no thrombosis in it.

Attention was then turned to the artery. After some deliberation, and in view of the definite clinical findings, it was decided to open the artery; this was done longitudinally through a 1-cm. incision, 4 cm. above the profunda. A free flow was obtained from above, moderately free flow from below. No thromboses or emboli were seen or extractable. The artery was then closed.

#### CLINICAL DIAGNOSES

Embolus to left femoral artery.

Hypertensive heart disease.

#### DR. WELCH'S DIAGNOSIS

Dissecting aneurysm of aorta.

#### ANATOMICAL DIAGNOSIS

Dissecting aneurysm of aorta.

#### PATHOLOGICAL DISCUSSION

DR. CASTLEMAN: At autopsy, we found an enlarged heart, weighing 700 gm. The coronary arteries showed a moderate degree of sclerosis but no evidence of occlusion. In the ascending aorta, several centimeters above the valve, was a T-shaped intimal tear in the intima, which communicated with a dissecting aneurysm. The ex-

ternal perforation had occurred just below this region into the pericardium, which was full of fresh blood. The dissection had continued down the aorta into the left external iliac and femoral arteries, to a point about 5 cm below Poupart's ligament, at which point the lumen was occluded by the opposing intimal surfaces. The incision at operation was a few centimeters below the point of occlusion. Had the surgeon known that this was a dissecting aneurysm at the time of operation, he might have attempted the operation described by Gurin,\* that is, the making of a nick in the occluding intima above, to allow the blood from the dissecting channel to come down and enter the original stream. This might have relieved the pressure in the aneurysm and perhaps prevented external rupture. In Gurin's case, the circulation of the leg was restored, but the patient died six days later.

There is one other thing that occurred in this case that is quite unusual. The external perforation through the adventitia must have been relatively slow, because the blood had extended from the adventitia of the aorta into the adventitia of the main pulmonary artery and its branches into both lungs, appearing as subpleural hemorrhagic extravasations in the interlobar septa. At present, we have not finished studying the microscopic sections, but we are quite certain that the etiology of the dissection was media necrosis aortica cystica. There were no atheromatous plaques or areas of arteriosclerosis in the ascending aorta at the site of the tear. There was no evidence of syphilis or of an inflammatory reaction that would go with syphilis. I might say, Dr Richardson, that syphilis

rarely, if ever, produces dissecting aneurysm.

DR RICHARDSON: My reasoning was false. I did not realize that a diastolic murmur could occur as a result of a dissecting aneurysm. If I had known this, I should not have mentioned syphilis.

DR BLAND: Was there any abnormality of the aortic valve, other than the deformity of the aortic ring, to account for the diastolic murmur?

DR CASTLEMAN: No.

DR BLAND: Dr. Chester S. Keefer once suggested that such a murmur might be due to the reflux of blood through the rent in the aorta, a possibility that seems to me most unlikely. I do not believe there is that much reflux of blood with diastole, unless possibly at a much later date when a double aorta has developed in the few who survive. The first explanation seems more reasonable. In perhaps a fourth of the cases, an aortic diastolic murmur appears immediately after the dissection.

Does syphilis of the aorta protect against this condition?

DR CASTLEMAN: I do not know. It is quite possible that the medial scars that are formed in syphilis might be a protection against it. We have never seen dissecting aneurysms of the aorta produced by syphilis.

DR BREED: May I ask again about the pain in dissecting aneurysm? Do you think the pain in this case was less? I am not trying to defend my diagnosis. I am asking for information.

DR BLAND: I should say that at least 90 per cent of patients have severe pain. Double barreled aortas are occasionally found post mortem, with no history of an acute illness corresponding to the dissection.

## POPULARIZATION OF ADVANCES IN MEDICINE

THE June 14 issue of *Science News Letter*, a weekly publication devoted to popularized accounts of advances in the sciences, makes the following startling introductory statement concerning papers presented at the Cleveland meeting of the American Medical Association: "*Six new successful treatments, promising relief or cure for the suffering of thousands of men and women, were reported. . . . Hundred per cent control of gonorrhea is made possible by sulfa drug. Crude liver extract is the new remedy for gout and arthritis. Salts of gold are being tried secretly on human rheumatism patients. Sex hormone treatment gives new hope for those with cancer of prostate gland. Iodized oil helps sinus disease, and x-rays are advised for Hodgkin's disease.*" As one reads the subsequent paragraphs, one is told that the drug,

sulfathiazole, has been responsible for 100 per cent cures of gonorrhea in three days; that the use of crude liver extract in the treatment of patients with gout and arthritis was promptly followed by a disappearance of symptoms, particularly in the former disease; that a gold compound, calcium aurothiomalate, has been successfully used in the treatment of experimentally produced arthritis in mice; that female sex hormones or castration inhibits the growth of cancer of the prostate; that the injections of iodized oil into the sinuses result in the subjective improvement of patients suffering from sinusitis; and that patients with Hodgkin's disease are relieved by x-ray or radium treatment.

In commenting on these abstracts, the medically trained writer could reasonably state that sulfathiazole is a standard accepted remedy for gonorrhea, although no one has ever before obtained 100 per cent effectiveness, a claim that requires careful follow-up studies over a period of months or years; that in judging the value of any new treatment for gout,—the present treatment is reasonably satisfactory,—the possibility of spontaneous remissions of the disease must be excluded; that experimentally produced arthritis in mice is undoubtedly a different disease from human arthritis, the cause of which is unknown; that the efficacy of the use of female sex hormones in the treatment of cancer of the prostate has been discussed, pro and con, for several years; that subjective improvement in patients with sinusitis is a poor yardstick for measuring the value of any therapeutic agent; and that x-rays and radium have been used for the treatment of patients with Hodgkin's disease for several decades. In other words, three of these "new, successful treatments" have been previously reported, two require confirmation of their value, and for one no claim for efficacy in human beings has been made. Undoubtedly many, if not all, of these points were brought out by the speakers at the meeting, and it is unfortunate that popularized reports in periodicals and newspapers are, in many instances, so garbled.

The public should, of course, be informed concerning advances in medicine, since lay education

of this sort is one, if not the most effective, means of promoting the health of the nation. However, such reports, particularly those in regard to widespread diseases such as gonorrhea, arthritis and sinusitis, should be accurate and conservative; if "successful remedies" are announced year after year, the layman will become suspicious, and lay support of the medical profession—a matter of vital importance at the moment—will be weakened.

### MEDICAL EXPLORERS

Nor a few physicians who have traveled extensively have returned home to write of their explorations and thus to give pleasure and instruction to their fellow colleagues and many others. Some have set out on scientific missions, such as Mungo Park, the young Scottish surgeon, whose *Travels in the Interior Districts of Africa* (1799) may still be read as a thrilling account of individual adventure. Other famous doctors described their travels for pleasure. Two may be mentioned: Richard Bright's *Travels from Vienna through Lower Hungary* (1818), an account of a post-graduate tour, illustrated with Bright's original drawings, and Thomas Hodgkin's *Narrative of a Journey to Morocco* (1866), the story of a trip with his patient, Sir Moses Montefiore. To these two groups must be added a third, composed of those describing a vacation tour or a particular service with the Army or Navy. In this category would fall the well-known book by Oliver Wendell Holmes, *Our Hundred Days in Europe* (1887), and the fine account by the late Harvey Cushing entitled *From a Surgeon's Journal* (1936).

The whole group of travel books by doctors extends into several thousand volumes. There have already been gathered in one library four or five hundred volumes, and many more are known. Doctors in general have added greatly to the knowledge of the world, and their reminiscences have been of much interest to their fellow colleagues. Few, however, have engaged in much more than the ordinary types of travel. Mungo Park would be considered an explorer of the first class, as would the American, Elisha Kent Kane, who visited the Arctic.

At the present time there must be added to these individuals the name of Richard Upjohn Light, who in the last ten years has made two unusual trips by aeroplane, accounts of which have been published. The first one was a privately printed book, *Journal of a Seaplane Cruise Around the World, August 20, 1934, to January 24, 1935* (1937). On this trip, Light, with Robert French Wilson as his radio operator, circumvented the globe by aeroplane, except for the trip across the Pacific from Manila to Vancouver. Thus he became the first American to fly from continental United States eastward to the Philippine Islands. His log of the journey was accompanied by his carefully drawn maps of the country over which he passed. He made many notes of particular medical interest, and one of his reports, after his visit to Labrador, was separately published in the October 25, 1934, issue of the *Journal*. In addition there are many notes in the book about medical conditions in Greenland and accounts of his visits to various hospitals in Europe. This journey, taken seven years ago, was a pioneer effort in exploration by aeroplane and was widely recognized by geographers as a trip of unusual importance. Following this exploration, Light was made a member of the American Geographical Society and later was elected a councilor of that distinguished scientific body.

Under the auspices of the American Geographical Society, Light has now published his account of another aeroplane trip, this time over Africa. A review of the extraordinary book appears in this issue of the *Journal*. His account is a fitting climax to an unusual career in the air, which began in 1930. Light flew over Central America in 1932; later he photographed parts of the Rocky Mountains from Vera Cruz in Mexico northward to Salt Lake City. His trip around the world in 1934-1935 has already been mentioned. In 1937-1938, prior to the trip across Africa, Light and his wife flew westward across North America, southward through Mexico and Central America, then eastward across South America to Rio de Janeiro. During this decade, Light has become the outstanding physician of his time in the world of aerial exploration.

## MEDICAL EPONYM

### HUTCHINSONIAN TEETH

On May 18, 1858, Jonathan Hutchinson (1828-1913) presented "Report on the Effects of Infantile Syphilis in Marring the Development of the Teeth" before the Pathological Society of London. This paper appears in the *Transactions of the Pathological Society of London* (9: 449-455, 1858).

For a considerable time past, I have been in the habit of recognising in a certain very peculiar development of the permanent teeth an indication that their possessor had in infancy suffered from hereditary syphilis. . . . I will now pass to the conclusions arrived at.

. . . . *There is a peculiar condition of the teeth, which results from the influence of hereditary syphilis, and . . . the most frequent features of this condition are the following:*—*a. Smallness.*—The teeth stand apart with interspaces, and are rounded and peggy in form instead of flat. *b. Notching.*—They usually exhibit in their border a broad shallow notch, or at times, two or three (serrated). Owing to their softness, these teeth rapidly wear away, and this notching is thus often obliterated, but when markedly present, it is one of the most decisive conditions. *d. Colour.*—Instead of the clear, smooth, white exterior of good teeth, they present a dirty greyish surface, totally destitute of polish and rarely smooth. No amount of cleaning will materially alter this feature which owes its existence, I believe to the great deficiency of enamel. *e. Wearing down.* As before observed their softness from deficiency of enamel renders them liable to premature wearing down. . . . *f. The signs mentioned apply almost exclusively to the incisors and canines and in fact the grinders are usually altered in a very much less degree. Their surfaces are often more uneven than those of healthy teeth, and now and then they present tubercular projections of a very peculiar character. . . . The above remarks apply only to the permanent set.*

### SECTION OF OBSTETRICS AND GYNECOLOGY\*

#### SUDDEN DEATH OF UNKNOWN CAUSE DURING THE SIXTH MONTH OF PREGNANCY

A twenty-seven-year-old para II had had no prenatal care. Physical examination during her first pregnancy, two years previously, was negative; the blood pressure and the heart and lungs were normal. There was no history of operation. The first pregnancy had terminated normally at term with a living child. The physician

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section. Letters should be addressed to Dr. Raymond S. Titus, Secretary, 330 Dartmouth Street, Boston.

who had attended the patient previously was informed of the present pregnancy very casually when making a visit at the house because the child had measles. He made no examination. A very short time after this, the patient complained of a severe pain and died before a physician arrived.

*Comment.* Since it is known that emboli during pregnancy cause death, it seems likely that such a condition was the cause of sudden death in this case. There was no history of heart disease. The patient had had a baby two years earlier, at which time the attendant physician said that her heart was normal. She had had no infections since then, so that it is fair to infer that there was no cardiac lesion. The blood pressure was said to have been normal with her first pregnancy, and consequently hypertension as a cause of cerebral hemorrhage can be ruled out. Furthermore, had she had a cerebral hemorrhage, it is unlikely that she would have died so quickly. It is said that she had a pain and died. It is not stated where the pain was localized. The uterus may rupture spontaneously at five or six months, but death occurring so quickly after the rupture is unlikely, and there was no history of vaginal bleeding.

It is unfortunate that the medical examiner did not insist that an autopsy be performed.

#### DEATHS

DOUGHERTY—HARRY L. DOUGHERTY, M.D., of Jamaica Plain, died June 1. He was in his forty-third year.

Born in Nickelsville, Virginia, he attended William and Mary College and received his degree from the University of Louisville School of Medicine in 1925. He served his internship at the United States Marine Hospital in Chelsea and then opened offices in Jamaica Plain. He was a member of the staff of the Faulkner Hospital.

Dr. Dougherty was a member of the Massachusetts Medical Society and the American Medical Association.

His widow, his parents, two daughters, two sons, three brothers and four sisters survive him.

NORTON—GEORGE P. NORTON, M.D., of Fitchburg, died June 12. He was in his sixty-eighth year.

Dr. Norton received his degree from the Bellevue Hospital Medical College, New York City, in 1895. He was former city physician and district medical examiner and had been on the staff of the Burbank Hospital for twenty-nine years. At the time of his death, he was chief medical examiner for the draft board under the Selective Service Act.

A former president of the Worcester North District Medical Society, he was also a member of the American Medical Association.

His widow, two sons, a daughter and a grandchild survive him.

TRACY—JOHN M. TRACY, M.D., of Springfield, died July 9. He was in his seventy-fourth year.

Born in Saugerties, New York, he attended St. Mary's College, New York City, and received his degree from George Washington University School of Medicine in 1898.

Dr. Tracy began practice in Springfield in 1899, where he was a former member of the School Committee and a member of the staff of the Mercy Hospital and the city health department. At the time of his death, he was a lieutenant colonel in the United States Army Medical Reserve.

He was a fellow of the Massachusetts Medical Society and the American Medical Association.

Two sons and a daughter survive him.

## MISCELLANY

### GASTRIC LAVAGE IN ADULTS

Failure to find tubercle bacilli in the sputum even after repeated examination of successive specimens, is no justification for ruling out the possibility of tuberculosis. The least certain of the methods commonly used is the staining of the direct smear of the untreated sputum. One supplementary method is to examine the stomach washings for tubercle bacilli especially in children, who are likely to swallow the sputum. Roper and Ordway (*Gastric Lavage in Adults with Pulmonary Tuberculosis*, *Am. Rev. Tuberc.*, 43:543-556, 1941) advocate its wider use for adults and offer impressive evidence of its value. Abstracts of their article follow.

The examination of fasting gastric contents by smears for tubercle bacilli, first reported in 1898, proved unreliable, and the need for culture and animal inoculation was demonstrated. Since 1927, numerous articles have been published regarding this procedure in juvenile tuberculous patients. More recently the test has been used on adults.

This report presents the findings obtained by guinea pig inoculations of fasting gastric contents of tuberculous and nontuberculous patients. By the addition of this procedure to the usual methods, recovery of tubercle bacilli in tuberculous patients was practically doubled.

The studies were carried out at the Metropolitan Life Insurance Company Tuberculosis Sanatorium during a three-year period in which approximately 1000 patients were admitted of whom 135 were diagnosed as having active pulmonary tuberculosis and the remainder were considered to be nontuberculous. This afforded opportunity for using controls.

Since 1929, the percentage of minimal cases admitted has almost trebled, in patients with moderately advanced disease it has decreased slightly, and in those with far advanced involvement it has declined to one-third the former figure. Yet the percentage of positive sputum cases has fallen despite the more frequent use of animal inoculation (from 45.2 per cent in the period 1926 to 1928 to 34.8 per cent in the period May, 1936 to May, 1939).

Of the 135 tuberculous patients of the present study, 34.8 per cent gave positive recovery by sputum examinations alone. The addition of gastric lavage almost doubled this percentage, namely, 63 per cent.

Sharp distinction is made between sputum and fasting stomach contents. Sputum refers to the bronchial secretion that is actually expectorated by coughing or clearing the throat. The gastric specimen contains the bronchial secretion which has gained entrance into the pharynx and has subsequently been swallowed. Gas-

tric lavage was initially employed in children because of their inability to expectorate. By means of this same test in adults, many positive results are obtained among those whose efforts to raise sputum are unsuccessful, as well as in many of those producing unsatisfactory or negative sputum.

Sputum produced by the tuberculous patient may contain tubercle bacilli on one day and none on the next. The same variability occurs with gastric washings. Stelm recommends that the test be given on each of three successive mornings.

The test is of assistance not only in the diagnosis but also in the management of the tuberculous patient. After years of treatment the sputum may disappear or become negative, whereas the gastric contents may still exhibit virulent tubercle bacilli.

The procedure of obtaining the gastric specimen causes only slight discomfort to most persons and is not harmful on the other hand repeated forceful voluntary efforts to expectorate are uncomfortable and may be harmful. The value of proving or disproving the clinical and roentgenologic diagnosis of pulmonary tuberculosis is obvious and of equal significance is the conclusive demonstration of the subsequent disappearance of tubercle bacilli from the bronchial secretions of tuberculous patients under treatment. Knowledge of these facts is of sufficient import to justify the use of gastric lavage whenever it is indicated by the absence or negativity of sputum.—Reprinted from *Tuberculosis Abstracts*, July, 1941.

## CORRESPONDENCE

### THE CLOSED STAFF HOSPITAL

To the Editor: An editorial in the June 5 issue of the *Journal* pointed out many of the advantages of the closed staff hospital but failed to mention any of the unsalutary practices that sometimes exist.

That any member of the medical profession who is technically equipped, adequately trained, ethical and desirous of keeping constantly up to date in his profession will have no difficulty in obtaining permission to practice in his local hospital is not always true. Members of medical boards who are responsible for nominations to the staff are not always actuated by purely altruistic motives. Prejudice, jealousy and ambition to increase their practice regardless of the Golden Rule may influence their decisions. Moreover, members of these committees are often self-perpetuating either by reason of their position as chiefs of services or because of their appointment by lay boards who govern the hospital. Nominations to the staff therefore are not always based on the considered judgment of the doctors' peers, since they are made by physicians who may not be responsible to or representative of the staff. As a result, members of medical boards may prohibit a physician from using the hospital for an indefinite time without just cause, thus interfering with his livelihood, preventing his professional development and results in inferior service to his patients.

The correction of these unfair practices is definitely the business of organized medicine such as the Massachusetts Medical Society. If physicians who serve on executive or advisory committees in hospitals could be elected by ballot by the entire staff for limited terms (possibly one to three years), it would not only reduce these discriminatory practices but also contribute to the democratic administration of hospitals as a whole. Such recommendation by the Massachusetts Medical Society would no doubt be received by hospital trustees or directors with

the same spirit of co-operation as were similar constructive suggestions by other reputable medical organizations, such as the American Medical Association and the American College of Surgeons.

CARL BEARSE, M.D.

Boston

## BOOK REVIEWS

*Focus on Africa.* By Richard Upjohn Light, M.D. Foreword by Isaiah Bowman, Ph.D., LL.D. 4°, cloth, 228 pp., with 323 illustrations and 14 maps. New York: American Geographical Society, 1941. \$5.00.

In the winter of 1937-1938, Dr. Richard Light, an explorer of note, who has traveled extensively in his airplane, and also a neurosurgeon, now in practice in Kalamazoo, Michigan, who was trained by Dr. Harvey Cushing, flew across Africa from Capetown to Cairo. His wife, who is also an expert in aviation, acted as co-pilot, radio-man and photographer. This extraordinary trip is now described in a narrative augmented by a series of superb photographs of the country over which he flew. Dr. Light writes in a delightful and informative style, and the book will make delightful reading for physicians interested in the broader aspects of medicine and travel.

Although there is not much strictly medical material in Dr. Light's account, nevertheless he gives sidelights on the people of South Africa and some of the problems connected with the immense industries of gold and diamond mining. In addition to the unusual photographs giving a new idea of the terrain of a country as viewed from the air, the book is illustrated by numerous maps carefully depicting the course of his flight. It may well be said, as noted by Dr. Isaiah Bowman, who writes a foreword to the book, that Dr. Light has put details "against their parent backgrounds, effects against their causes" in an admirable and graceful manner. He is indeed one of the leaders of modern exploration whose standard is "To broaden those earth-bound glimpses. . . ."

*Lipidoses: Diseases of the cellular lipid metabolism.* By Siegfried J. Thannhauser, M.D., Ph.D. Edited by Henry A. Christian, M.D., LL.D., Sc.D. (Hon.), F.R.C.P. (Hon., Can.). (Reprinted from *Oxford Loose-Leaf Medicine*.) 8°, cloth, 370 pp., with 78 illustrations. New York: Oxford University Press, 1940. \$6.00.

Harvey Cushing once remarked that the field of general surgery at first appealed to him as being most worth while to master; before long he realized that surgery of the central nervous system was less well understood and therefore was more appealing. This quickly proved to be too broad an area for his temperament, and hence surgery of the brain became of paramount importance. But the brain was too large so that next its center, the pituitary gland, attracted his main attention; finally the secrets of the anterior lobe of this small body proved sufficiently elusive to satisfy his medical inquisitiveness. This is a good story of how zeal to make important discoveries in a small corner of medicine is often developed.

The author of this book evidently feels about medical research as Cushing did. For he began as a competently trained teacher and investigator of general medicine; his imagination became stimulated by how little was known of the general subject of the lipids, and this book is the crystallization of twenty years of painstaking, critical study of the matter.

The Oxford University Press always publishes stylishly. Hence the format of the volume is excellent. The type is easy and agreeable to read, the illustrations on the whole are clear, and the job of indexing is well done. The plan of the work, too, is easily comprehensible: first a discussion of the physiology and chemistry of lipid metabolism; next a chapter on hyperlipemia; then chapters on the xanthomatoses, primary, secondary or localized; and finally two concluding chapters on those confusing diseases known familiarly to the well read as Gaucher's disease and Niemann-Pick's disease. A scholarly bibliography of some eight hundred references is neatly dovetailed in between each chapter. The net result is a fine monograph that will serve for the next several years as the standard work of reference about unique disorders caused by disturbances in the metabolism of fat.

*Photodynamic Action and Diseases Caused by Light.* By Harold F. Blum, Ph.D. 8°, cloth, 309 pp., with 25 tables and 50 illustrations. New York: Reinhold Publishing Corporation, 1941. \$6.00.

This book justifies the two distinct purposes that prompted the American Chemical Society to sponsor a series of scientific and technologic monographs on chemical subjects. First, it closely connects the fields of physics, chemistry and medicine in the study of photodynamic action and diseases caused by light. Secondly, it presents a thorough historical survey of the progress already made, and points out directions in which research should be extended.

This study is vastly important at a time when industry is introducing many new chemicals, especially dyes, in our defense program. Their possible toxicity in relation to light has been recently described. This deleterious combination has been recognized for almost the past five decades, but has been neglected by most physicians. The author's attempts to correct or clear many incorrect or vague statements in the literature are worth while. Many diseases have been ascribed without proof to the action of sunlight. Other diseases are readily recognized in certain endemic areas, but are missed in other places because of ignorance of their existence. Few physicians recognize this sensitivity to light among human beings. Today, with the widespread use of ultraviolet radiation and the increase in the use of photodynamic substances for diagnostic purposes and in chemotherapy, physicians should be alert and cognizant of their possible effects when the patient is subjected to sunlight, to radiation from mercury-vapor lamps and carbon-arc lamps and to roentgen rays, for great damage can be done. Dermatologists have been more or less aware of the untoward results that occur after the unfortunate use of these substances without knowledge of them. This has been demonstrated in the use of dyes and ultraviolet radiation in the treatment of psoriasis, and their use in cosmetics and industrial chemistry.

The book is divided into four parts: the introduction describes the nature of radiation and its general biologic effects; the second part presents the general photochemical aspects of photodynamic action; the third section describes the diseases caused by light in domestic animals; and the fourth part describes the diseases produced by light in man. Each phase is adequately treated, and each part can be read independently.

It is a book that can be found useful by all students, and it should be in the library of all physicians and veterinarians.

## THE ARNOLD-CHIARI MALFORMATION\*

### Diagnosis, Demonstration by Intraspinal Lipiodol and Successful Surgical Treatment

RAYMOND D. ADAMS, M.D.,† RICHARD SCHATZKI, M.D.,‡ and  
W. BEECHER SCOVILLE, M.D.§

BOSTON

TWO patients who at operation were found to have a malformation of the cerebellum were recently admitted to the Neurological Service at the Massachusetts General Hospital. The rarity of the syndrome, the discovery of the importance of intraspinal lipiodol as a diagnostic method,

since they worked separately, both have been credited with making the first observation. Later, Gredig and Schwalbe<sup>3</sup> published a scholarly account of the embryology and anatomy of this anomaly, and Russell and Donald<sup>4</sup> and Penfield and Coburn<sup>5</sup> have recently discussed the pathologic physiology.

The chief characteristics of the anomaly as given by these different writers are:

It is primarily a congenital malformation of the medulla oblongata and the cerebellum, both of which are herniated through the foramen magnum into the cervical spinal canal (Fig. 1). The part of the cerebellum that is herniated is the inferior portion of both hemispheres, improperly called the "tonsils."

This herniation secondarily leads to the following disturbances: obstruction to cerebrospinal fluid circulation resulting in hydrocephalus—the cerebrospinal fluid passes from the ventricles into the spinal canal and cannot re-enter the cranial vault, where it is normally absorbed, because of the mass of tissue obstructing the foramen magnum; stretching and injury of the lower cranial nerves; pressure on the spinal cord and the medulla oblongata; and deformity of the cerebellum.

An associated meningocele, together with the Arnold-Chiari malformation, causes most of the patients to die in infancy.

The basal meninges, particularly the pia and arachnoid, are greatly thickened.

Even though this is a rather clear-cut pathologic entity, the Arnold-Chiari malformation is usually discovered at necropsy, not having been suspected during life.

In the last few years, Parker and McConnell<sup>6,7</sup> and Aring<sup>8</sup> have reported a group of patients

FIGURE 1. Diagram of Brain Stem and Cerebellum in Sagittal Section.

and the need of emergency surgery in the treatment of these cases have prompted us to present them in detail.

Arnold,<sup>1</sup> in 1894, and Chiari,<sup>2</sup> in 1895, published original descriptions of this malformation, and

who during adolescence and early adulthood presented a symptom complex suggestive of a posterior-fossa or high-cervical tumor, but who at operation were found to have the same deformity of the medulla oblongata and cerebellum that Arnold and Chiari had described. These patients did not have a meningocele or other congenital anomalies, and several survived after suboccipital and high-cervical decompression. There was marked thickening of the basal leptomeninges. Whether the deformity of the cerebellum in these cases is also a congenital anomaly is less certain.

The first of our patients is representative of the type of case described by Parker and McConnell; the second illustrates the type described by Arnold and Chiari. We are using the term "Arnold-Chiari syndrome" to designate the aggregate of symptoms and signs by which this malformation manifests itself.

### CASE REPORTS

CASE 1. J.P. (No. 89142), a 17-year-old schoolboy, was admitted to the Neurological Service of the Massachusetts General Hospital with the following symptoms: suboccipital discomfort, periodic nausea and vomiting, and unsteadiness of gait. Ten months before entry, he sustained a slight head injury when he dived into shallow water. As well as he could remember, his head struck the bottom of the pool, but he was only dazed by the incident and had no difficulty in getting out of the water. The following day, his neck was sore and stiff, and there were pains at the base of his skull. When directly questioned about this symptom, he admitted to having had similar pains for at least 2 years prior to that time. From the date of the injury until admission to the hospital, the headaches became severer and more persistent. Anorexia, nausea and vomiting were frequent symptoms. Three months before admission, the patient fainted and was taken to a local hospital, where a physical examination and x-ray study of the cervical spine disclosed nothing abnormal. He began to have difficulty in walking, owing to stiffness and unsteadiness of his legs. Several times he became choked on food and had trouble drinking water. His speech had always been slurred. Weight loss had amounted to about 25 pounds and was attributed to the nausea and vomiting.

On examination, the blood pressure was 110/94, the temperature 98°F., the pulse 60, and the respirations 16. The patient was a tall, undernourished boy of asthenic habitus. The head and neck were held in a rigid posture but were well centered. He turned his body when looking to either side, and any sudden motion of the head was resisted, because of the pain thus produced. There was very slight but definite blurring of the optic-disk margins, and obliteration of the optic cups. The pupillary reflexes were normal, and ocular movements full. Jaw strength was good, and the sensation over the face was normal. Both sides of the face moved equally in mimicry and laughter. The jaw jerk was hyperactive. No disturbance of either division of the eighth cranial nerve was noted. Two days before operation, the patient

was unable to swallow either solid foods or liquids without choking. The sternomastoid and trapezius muscles were of good strength, but the tongue was weak and tremulous, though not atrophied. The speech was somewhat slurred but could have passed for normal. There was an unsustained and at times sustained horizontal nystagmus on both right and left lateral fixation of gaze. There was a slight terminal tremor in doing the finger-nose test, and the muscle tone in the arms seemed diminished. Tests of rapid alternating movements were done well. He tended to walk with a wide base and to deviate to either side. Heel-knee tests were performed with a minimum of unsteadiness. Sensation over the entire body was normal. The tendon reflexes were equal and slightly hyperactive; the abdominal reflexes were absent. There was urinary retention for 24 hours preceding operation.

The blood-cell counts and the urine were normal. Hinton and Wassermann reactions were negative on both serum and spinal fluid. The lumbar puncture showed *almost complete dynamic block*. Two days later, this was repeated with the same results. The total protein on the cerebrospinal fluid was 78 mg. per 100 cc.; the gold-sol curve was 0012210000, and there were no cells.

X-ray examination of the dural canal after lumbar injection of 5 cc. of lipiodol showed that the lipiodol could be freely moved through the lumbar and dorsal as well as the lower cervical spine. It met with obstruction at the upper edge of the 3rd cervical vertebra, the obstruction being cap shaped. The outline of the cap was hazy and not so distinct as that normally seen in complete obstruction of the spinal canal. No lipiodol was seen to pass beyond the obstruction during fluoroscopic examination of 10 minutes' duration, the patient being examined with his head hanging down at a tilt of 65°. Films taken 10 minutes later showed that some lipiodol had passed by the obstruction and lay in the interpeduncular cistern (Figs. 2, 3 and 4). The amount of lipiodol in the cerebral cavity increased during the next hour, although the patient stayed in horizontal position during this time. A definite upper edge of a tumor mass could not be demonstrated during examinations, which extended over 96 hours, although some lipiodol was constantly visible above the lesion when the patient was in the erect position. The conclusions were as follows:

The picture is very unusual. The obstruction with cap formation is in favor of a mass in the upper cervical area. There are, however, several features that are unusual for a tumor: the edge is not so distinct as one usually sees in tumor; the lobulation is more pronounced than that seen in tumor; an upper edge of the tumor is not demonstrable, although lipiodol is present above the area of obstruction; and the passage of lipiodol into the cranial vault is comparatively easy for a tumor of this size — there seems to be some kind of valve mechanism allowing the lipiodol to move with comparative ease upward into the skull but not downward from there into the cervical spine.

In spite of these unusual features, the preoperative diagnosis was tumor of the cervical cord, with extension into the posterior fossa.

At operation, performed by Dr. John S. Hodgson and Dr. W. Beecher Scoville, the dura was opened, and what appeared to be normal cerebellar tissue presented itself down to the level of the 3rd cervical vertebra. The arch of the foramen magnum, as well as the bone over the mid-occipital region, was removed, exposing the

cerebellum. The cerebellar hemispheres were small and atrophic and were situated high in the posterior fossa. From the lower portion of the cerebellum, there projected downward two parallel fingerlike processes that overlaid the dorsal surface of the medulla and upper cervical cord. These processes were densely adherent

and the overlying muscles and skin were closed without drainage.

The patient withstood the operation fairly well, although at the beginning he had a slow pulse and a respiration rate of 10 per minute. For the first hour after the operation, he had generalized muscular tremors. His

both to the spinal cord and to each other. A large vessel with many branches filled the cleft between the two tonsillar projections. By measurement, the fingerlike projections extended a distance of 4 cm. into the cervical canal. An effort was made to pass a catheter between the processes and the cord so as to enter the 4th ventricle and aqueduct, but this proved impossible. Jugular compression was made, and normal spinal fluid oozed slowly from beneath and at the sides of the tonsillar projections of the cerebellum. The dura was left wide open,

convalescence proved to be slow and difficult. During the first 2 postoperative days, his respirations were slow (6 to 8 per minute), uneven and stertorous. Repeated inhalations of 5 per cent carbon dioxide in oxygen increased the rate to 14 per minute. Dysphagia was present for several days. Later he developed an acute epididymitis and an acute otitis media. Before discharge, films of the entire spinal column were taken and showed absence of spina bifida. On the 40th postoperative day, the patient was discharged. At that time his headaches

who during adolescence and early adulthood presented a symptom complex suggestive of a posterior-fossa or high-cervical tumor, but who at operation were found to have the same deformity of the medulla oblongata and cerebellum that Arnold and Chiari had described. The tendon reflexes were equal and slightly hyperactive; the abdominal reflexes were absent. There was urinary retention for 24 hours preceding operation.

The blood-cell counts and the urine were normal. Hinton and Wassermann reactions were negative on both serum and spinal fluid. The lumbar puncture showed almost complete dynamic block. Two days later, this was repeated with the same results. The total protein on the cerebrospinal fluid was 78 mg. per 100 cc.; the gold-sol curve was 0012210000, and there were no cells.

X-ray examination of the dural canal after lumbar injection of 5 cc. of lipiodol showed that the lipiodol could be freely moved through the lumbar and dorsal as well as the lower cervical spine. It met with obstruction at the upper edge of the 3rd cervical vertebra, the obstruction being cap shaped. The outline of the cap was hazy and not so distinct as that normally seen in complete obstruction of the spinal canal. No lipiodol was seen to pass beyond the obstruction during fluoroscopic examination of 10 minutes' duration, the patient being examined with his head hanging down at a tilt of 65°. Films taken 10 minutes later showed that some lipiodol had passed by the obstruction and lay in the interpeduncular cistern (Figs. 2, 3 and 4). The amount of lipiodol in the cerebral cavity increased during the next hour, although the patient stayed in horizontal position during this time. A definite upper edge of a tumor mass could not be demonstrated during examinations, which extended over 96 hours, although some lipiodol was constantly visible above the lesion when the patient was in the erect position. The conclusions were as follows:

The picture is very unusual. The obstruction with cap formation is in favor of a mass in the upper cervical area. There are, however, several features that are unusual for a tumor: the edge is not so distinct as one usually sees in tumor; the lobulation is more pronounced than that seen in tumor; an upper edge of the tumor is not demonstrable, although lipiodol is present above the area of obstruction; and the passage of lipiodol into the cranial vault is comparatively easy for a tumor of this size — there seems to be some kind of valve mechanism allowing the lipiodol to move with comparative ease upward into the skull but not downward from there into the cervical spine.

In spite of these unusual features, the preoperative diagnosis was tumor of the cervical cord, with extension into the posterior fossa.

At operation, performed by Dr. John S. Hodgson and Dr. W. Beecher Scoville, the dura was opened, and what appeared to be normal cerebellar tissue presented itself down to the level of the 3rd cervical vertebra. The arch of the foramen magnum, as well as the bone over the mid-occipital region, was removed, exposing the

in circumference (occipitofrontal). There was a scar over the spine in the lumbosacral region, and ptosis of both eyelids. Visual acuity, visual fields and optic fundi were normal. There was bilateral weakness of facial muscles, more marked on the right than on the left. Lateral conjugate deviation of eyes to both right and left was very poor. There was coarse, well-sustained syn-

gait was very ataxic. The only sensory loss was over the 5th lumbar and 5 sacral dermatomes, where all modalities were affected. Tendon reflexes were slightly hyperactive in the arms, but in the legs, knee jerks were diminished and ankle jerks were absent. Abdominal reflexes and extensor plantar responses were absent.

X-ray examination showed a large head and increased

The double arrows represent lipiodol in the vault. 1 represents fillings in teeth; 2, the floor of the nasal cavity; and 3, the frontal sinuses.*

chronous nystagmus with the eyes at rest, which was increased by looking to either side or upward. Upward gaze was normal; convergence was poor. Speech was slurred, and there was slight dysphagia at times. There was weakness of hand grips, all movements of fingers and the flexors and extensors of the wrists. The interossei were atrophied, especially on the left. There was slight scoliosis to the left. Varus deformities of the feet, with weakness in dorsal and plantar flexion, were present. The

convolucional markings, and spina bifida in the lumbosacral region. Lumbar puncture revealed complete dynamic block on jugular compression, but good rise with abdominal pressure and cough. The spinal fluid, which had an initial pressure of 110 mm., was slightly xanthochromic; the total protein was 103 mg. per 100 cc., and the gold-sol curve 0000111000. A pneumomyelogram was unsuccessful.

While we were waiting to inject lipiodol into the spinal

canal and confirm the diagnosis of meningocele with Arnold-Chiari syndrome, the patient very rapidly became stuporous and soon was deeply comatose. An emergency operation, performed that night, consisted in suboccipital craniotomy and high-cervical laminectomy. A malformation of the hindbrain was found. The cerebellum projected into the cervical canal to the level of the second vertebra, and the medulla was displaced downward so that the cervical roots had to pass upward to where they made their exit through the intervertebral canals. Adhesions of the arachnoid and pia were very dense and were broken whenever possible. Convalescence was uneventful; the patient had no more headaches, the gait was improved, and when the patient was last seen in the Out Patient Department, 6 months after operation, the rest of the neurologic signs were stationary.

### DISCUSSION

These cases were clinically similar. In general, the symptoms can be classed under the following headings.

*Increased intracranial pressure.* Both patients, like many of those reported by Parker and McConnell,<sup>6,7</sup> had occipital headaches. Usually, the headache is occipital, suboccipital and cervical in location, comes on suddenly and is of several hours' duration, is aptest to occur during the night or in early morning, and sometimes causes a change in state of consciousness, such as fainting. The headache resembles in most respects the cerebellar-tumor headache. Both our patients had vomited with the headaches, and one was nauseated for several months. One patient had slight papilledema. Usually, the papilledema in this syndrome is not so marked as that in cases of cerebellar tumor.

*Involvement of several of the cranial nerves.* Sometimes the medulla is displaced so far into the spinal canal that the lower cranial nerves must pass through the foramen magnum to enter the cranial vault. Thus they are greatly stretched and often pinched as they go through the foramen magnum. Practically any one or several of the cranial nerves may show signs of injury, especially the lower ones. Our first patient had signs pointing to lesions of the seventh, ninth, tenth and twelfth cranial nerves bilaterally; the other had lesions of the third, seventh, ninth and, questionably, the twelfth.

*Compression of the brain stem.* The nausea and vomiting are usually attributed to medullary compression, as with cerebellar tumors. Other signs, such as disturbances of conjugate movements of the eyes and vertical nystagmus, are thought to be caused by intramedullary or intrapontine lesions.

*Compression of the spinal cord.* Both patients had bilateral pyramidal-tract signs; others have had

sensory disturbances. Of course, these signs could as well be due to compression of the brain stem. The marked weakness and atrophy of the hands in Case 2 is difficult to explain unless one postulates a small hydromyelia in the cervical cord. Other observers have found such lesions at necropsy.

*Cerebellar signs.* Symptoms suggesting cerebellar involvement may be the most striking part of the neurologic picture, or may consist of only slight gait disturbance, intention tremor or incoordination of movement.

Several neurologic conditions enter into the differential diagnosis of the Arnold-Chiari syndrome. Depending on whether the cerebellar symptoms, the cord symptoms or the intracranial-pressure symptoms are most marked, one considers cerebellar tumor, syringomyelia and syringobulbia, high cervical-cord tumor, — which extends through the foramen magnum into the posterior fossa, — intrapontine or intramedullary tumor, chronic adhesive arachnoiditis, cerebellar degeneration and platybasia. When the patient exhibits signs of a lesion involving several cranial nerves, the cerebellum, and the brain stem and of increased intracranial pressure, together with significant cerebrospinal-fluid findings (see below), most of the diagnostic possibilities are excluded. The neurologic diseases that should offer most difficulty in differential diagnosis are chronic adhesive arachnoiditis and platybasia.\* The latter is a deformity of the occipital bone and foramen magnum, and may produce pressure on the medulla oblongata and adjacent parts of the central nervous system, causing a clinical picture almost identical with the Arnold-Chiari syndrome. It is interesting to note that some degree of platybasia is often found in the Arnold-Chiari syndrome; in all probability it is an associated congenital anomaly of the skull. Nearly all the neurologic diseases considered in differential diagnosis lead to surgical exploration of the posterior fossa or cervical spinal canal; therefore, a diagnostic error is not serious.

Two laboratory procedures were found to be of diagnostic aid: lumbar puncture† and myelography. Lumbar puncture showed a complete block in the dynamics of cerebrospinal fluid, that is, jugular compression caused no rise in spinal-fluid pressure, although coughing, straining and

\*This congenital anomaly of the skull, also called "basilar impression," consists in an upward protrusion of the occipital bone around the foramen magnum, and is recognizable because major portions of the axis are above a line that connects the posterior edge of the hard palate with that of the foramen magnum.

†Caution should be taken in doing a lumbar puncture, because a very marked pressure change may cause medullary compression, thus endangering the patient's life. The information gained by this procedure probably justifies its careful use as a diagnostic measure but only after all other procedures are completed. Cisternal puncture is contraindicated.

abdominal pressure gave a prompt rise in pressure. The protein of spinal fluid was significantly increased. These findings are of course not specific for the Arnold-Chiari syndrome but only of a block in the cervical spinal canal. The intraspinal injection of lipiodol gives a very interesting and almost diagnostic picture, since it outlines the bifid projection of the two herniated cerebellar hemispheres.

The following description of the myelographic appearance of the protruding cerebellar tonsils seems to be characteristic of the lesion.

A mass within the upper cervical area produces a fairly marked block to lipiodol injected below the lesion. The block is less complete than one would expect from a tumor of similar size, the passage into the vault being less impaired than that in the reverse direction.

The outline of the mass is less distinct than that of tumor, owing to the sloping surface of the soft cerebral tonsils.

The edge of the mass shows lobulation produced by the gyri of the prolapsed cerebellum.

There seems to be a small central incisura within the mass corresponding to the incisura between the two cerebral tonsils.

Some degree of platybasia may be present.

A pneumomyelogram was attempted in Case 2, but was unsuccessful. In the future, this may replace the lipiodol method.

Most neurosurgeons have unsuccessfully operated on these patients. The patient often fails to regain consciousness or dies suddenly some time during convalescence, presumably from compression of the medulla. Probably the wise treatment is to decompress the cervical spinal cord and cerebellum but not to attempt to liberate the nerve structures in the posterior fossa from the arachnoidal adhesions. Any manipulation that causes a sudden change in the spatial relations of these structures may lead to death. Both our patients survived the operation, fortunately, even though more than a simple decompression was done. Pre-

operative ventricular drainage, as suggested by D'Errico<sup>9</sup> in the treatment of hydrocephalus associated with spina bifida, was not attempted.

#### SUMMARY AND CONCLUSIONS

The Arnold-Chiari malformation is a congenital anomaly in which the cerebellum and medulla oblongata are partially displaced into the spinal canal. Certain cases have an associated meningo-myelocele or platybasia.

Two cases of Arnold-Chiari malformation are reported, one with and one without meningo-myelocele.

The symptoms are divided into five groups: those due to increased intracranial pressure; to involvement of several of the lower cranial nerves; to compression of the medulla oblongata and pons; to compression of the spinal cord; to deformity of the cerebellum.

The differential diagnosis should include such possibilities as high cervical-cord tumor, cerebellar tumor, cerebellar degenerative disease, tumor of the medulla or pons, chronic adhesive arachnoiditis and platybasia.

Lumbar puncture gives confirmatory evidence of the protrusion of the inferior portions of the cerebellar hemispheres into the spinal canal, that is, increased protein and signs of dynamic block.

Röntgenographic examination after intraspinal injection of lipiodol demonstrates a highly characteristic picture of the pathologic process.

## MICROCYTIC, HYPOCHROMIC ANEMIA, ASSOCIATED WITH SPLENOMEGALY AND REFRACTORY TO TREATMENT\*

### Report of a Case

LEONARD P. ELIEL, M.D.,† AND THEODORE B. BAYLES, M.D.‡

BOSTON

**I**N the course of observations on the hypochromic anemia of active rheumatoid arthritis, a thirty-nine-year-old Italian woman was encountered with a blood disorder characterized by severe hypochromia and microcytosis resistant to iron therapy, a blood smear showing basophilic stippling, polychromatophilia, target cells§ and marked anisocytosis and poikilocytosis, increased resistance of the red blood corpuscles to hemolysis in hypotonic salt solution, splenomegaly and an elevated serum bilirubin.

Wintrobe et al.<sup>1</sup> have recently reported a somewhat similar blood disorder in five persons over thirty-nine years of age, none of whom, however, had anemia of the severe degree shown by our patient.

The findings in our patient and in the members of her family are given below.

*The Patient.* J. A., a 39-year-old American-born Italian widow, was admitted to the Robert Breck Brigham Hospital in February, 1940, complaining of migratory, intermittent pain and swelling of the joints of 4 years' duration. Her father and mother were born in Italy and died in old age of a "stroke" and "ulcer of the leg" respectively. The past and system histories were not remarkable, except as presented in the present illness.

For 4 years, the patient had complained of painful swelling in the feet, ankles, knees, fingers and wrists. These symptoms seldom lasted more than a day and left no residual stiffness or disability; they were aggravated by wet weather and had recently become severe enough to interfere with her housework.

The patient stated that she had been "anemic" as long as she could remember. As a child, from about the ages of 7 to 10, she had "spleen trouble," at which time her abdomen was said to have been swollen periodically and to have become normal after the application of "plasters." Her older brother stated that she looked pale at that time, and that the family physician had said she had a very large spleen. These episodes, so far as the patient knew, were not attended by jaundice, chills, fever, nausea or vomiting. She had no more abdominal swelling after childhood. At the age of 8, she had a tapeworm of unknown variety, which was expelled after the administration of small pearl-like pills. She had never had any significant epistaxes, nor had she vomited any blood or coffee-grounds material. Bloody or tarry stools, hematuria, menorrhagia and metrorrhagia were absent, as were episodes of abdominal or back pain, vomiting, chills, fever

or jaundice. The patient had never had malaria. There was never a sore mouth or tongue, anesthetics or paresthesias; the appetite was good, and the bowel movements were regular, without diarrhea.

The patient had been a city-welfare case; she ate meat once or twice a week, but few colored vegetables or fruits and no whole-grain cereals, milk or eggs. Her alcoholic intake was very moderate. There was no history of exposure to benzol, lead, hair dyes, arsenic or commercial solvents. She never took cinchophen or other drugs for her joint pains, although she used acetylsalicylic acid occasionally for discomfort.

Physical examination showed a short, pale, somewhat stocky woman who appeared well and was in no great discomfort. The tongue was of normal color and not atrophic. The mucous membranes and conjunctivas were pale. The heart and lungs were normal. The abdomen was normal, except that the spleen was felt to descend on inspiration 3 cm. below the costal margin; its edge was very firm, nontender and smooth. The liver edge could not be felt. There was minimal periarticular thickening about the wrists and knees, and limitation of flexion of both little fingers. A neurologic examination showed normal reflexes and no sensory disturbances.

The blood showed a red-cell count of 4,300,000 with a hemoglobin of 7.9 gm. per 100 cc. of blood and a hematocrit reading of 30 per cent, and a white-cell count of 7600. A differential white-cell count was essentially normal. The blood smear showed marked variation in size and shape of the red cells, and there were a large number of microcytes, some well filled with hemoglobin. Many larger cells were markedly hypochromic. There were numerous pear-shaped and band-shaped, tailed, elliptiform and target cells. There were occasional cells showing polychromatophilia, and other cells with basophilic stippling. Smears at different times during hospitalization showed no normoblasts, but they were occasionally present (0 to 4 per 100 leukocytes) after the injection of epinephrine. Reticulocyte counts averaged 1 per cent. The platelets were normal to increased in number. Subsequent examination revealed that the color index was 0.51, the mean corpuscular volume 61.2 cubic microns, the mean corpuscular hemoglobin 15.9 micrograms and the mean corpuscular hemoglobin concentration 25.9 per cent. The serum bilirubin was 1.3 mg. per 100 cc., with an indirect van den Bergh reaction. A fragility test showed hemolysis beginning at 0.44 per cent saline solution, becoming definite at 0.28 to 0.32 per cent and complete at 0.12 per cent—a control showed beginning hemolysis at 0.44 per cent, becoming definite at 0.38 to 0.40 per cent and complete at 0.28 per cent. A test for urine urobilinogen with Ehrlich's reagent in serial dilutions of urine showed no urobilinogen beyond a dilution of 1:4 (control 1:8). Examination of wet films again showed the many bizarre forms seen in the smear, with many unusually flat irregular cells; there were no spherocytes. An anaerobic preparation failed to develop sickling of the red cells. No malarial parasites were seen.

\*From the Medical Service, Robert Breck Brigham Hospital.

†Formerly, student house officer, Robert Breck Brigham Hospital.

‡Research fellow, Robert Breck Brigham Hospital.

§Within the usually clear central area of the erythrocyte, there is a small island (bull's-eye) of hemoglobin, hence the resemblance to a target.

The serum protein, albumin globulin ratio, nonprotein nitrogen and fasting cholesterol were all normal. An analysis of fasting gastric contents showed 5 units of free and 6 units of total acid, after lusting, 82 units of free and 85 units of combined acid. The basal metabolic rate was -23 per cent, and following 2 weeks of therapy with 0.1 gm of thyroid daily was -12 per cent. Seven urine examinations showed nothing abnormal. Six stool examinations were negative for occult blood, and three revealed no parasites or ova.

During the patient's stay a sternal bone marrow biopsy

hyperplasia of normoblastic type, with a large increase in nucleated erythrocytes.

X-ray study showed bone changes consistent with mild rheumatoid arthritis. A skull plate was normal. There was no rarefaction or thinning of the cortex of the long bones. Thick and thin barium meals showed no gastric or esophageal varices or gastric or duodenal ulcer. A plain film of the abdomen showed the spleen to be enlarged.

During the patient's hospital stay and until August 13,

was performed, and through the courtesy of Dr J Beach Hazard, reported as follows:

The marrow is of markedly increased cellularity, only about 10 per cent of fat cells being evident per field, as compared with the normal. Scattered megakaryocytes are present and appear in about normal number. The increase in cells is due for the most part to an increase in nucleated erythrocytes, either pyknotic or normoblastic. There is no increase in stem cells or megakaryoblasts. A differential count based on 600 cells is as follows: stem cells, 1 per cent; blasts, 10 per cent; nucleated red cells, 69 per cent (21 per cent normoblasts, 48 per cent pyknotic nucleated red cells), polymorphonuclear neutrophils, 10 per cent; polymorphonuclear eosinophils, 3 per cent; eosinophilic myelocytes, 5 per cent; and neutrophilic myelocytes, 2 per cent. Diagnosis: marked erythrocytic

1940, she was given in addition to thyroid, as above, ferrous sulfate, brewer's yeast, ascorbic acid and haliver oil. She received the routine orthopedic care, including postural exercises, occupational therapy, wax to her hands, Castex wristlets and beaver board under her mattress. Her course was uneventful. She was free from complaints soon after her arrival and was discharged in March. Since discharge, she has continued the therapy given during her hospital stay, but the blood findings have remained essentially unchanged from those at discharge (Table 1).

**The Patient's Children** M F, a 21-year-old married daughter, had always been well. A stained blood smear showed slight variation in size of the red cells, with occasional tailed or banded forms. A very rare macrocyte was seen, in addition to slight polychromatophilia. The remainder of the findings are shown in Table 1. This patient did not have her mother's blood disorder.

Jul. A., a 17-year-old daughter, had always been well. Her blood examination revealed a red-cell count of 5,370,000 with a hemoglobin of 12.3 gm. per 100 cc. and a hematocrit reading of 40 per cent. The color index was 0.75, the mean corpuscular volume 74.5 cubic microns, the mean corpuscular hemoglobin 22.8 micromicrograms and the mean corpuscular hemoglobin concentration 30.7 per cent. The smear showed slight but definite variation in size, and rare microcytes and band-formed, elliptiform, tailed and pear-shaped cells consistent with the degree of secondary anemia present. One target cell was seen in counting 200 white cells. The reticulocyte count was 0.8 per cent. There was no polychromatophilia or basophilic stippling. The differential leukocyte count was normal. A serum bilirubin was normal. A fragility test showed hemolysis beginning at 0.44 per cent saline solution, becoming definite at 0.42 per cent and complete at 0.30 per cent; a control blood showed identical hemolysis. Skull roentgenograms were normal.

Because of the blood smear and the degree of anemia, a course of iron therapy was given to discover if the changes in the stained blood smear were those secondary to a simple iron-deficiency anemia or related to the blood disorder of her mother. For 6 weeks, this girl took 0.7 gm. of ferrous sulfate daily, and examination of her blood at the end of that time pointed toward a simple iron-deficiency anemia (Table 1); there were fewer larger cells, better filled with hemoglobin, and the stained blood smear had changed slightly but definitely toward normal.

*The Patient's Brothers.* F.Y., a 54-year-old tavern keeper, had always been well. A stained blood smear was normal, and other laboratory studies (Table 1) were all within normal limits.

M.Y. had died, at the age of 49, of epidermoid carcinoma of the lung. Except for mild asthma and emphysema preceding his terminal illness, a gonorrheal infection and a head injury, his history was not remarkable. Only an admission blood was recorded during his terminal illness; it showed a red-cell count of 5,050,000 with a hemoglobin of 95 per cent (Tallqvist), as shown in Table 1. An autopsy was limited to the operative wound, and no bone-marrow samples were studied.

*The Patient's Sister.* Mrs. C.H., aged 52, had always been well; her blood was normal.

### DISCUSSION

From examination of the data, it can be seen that the patient suffered from a marked microcytic hypochromic anemia with a majority of microcytic hypochromic cells and, in addition, an impressive minority of macrocytic hypochromic cells with an irregular distribution of hemoglobin. There was evidence of marked bone-marrow activity, as indicated by the presence of polychromatophilia, basophilic stippling, normoblasts and young white cells. The increase of the young red-cell

elements after the injection of epinephrine, and the bone-marrow biopsy showing a profusion of normoblasts, confirmed this impression. There was a chronic mild bilirubinemia. The increased resistance of the red cells to hemolysis in hypotonic saline solution was consistent with the degree of microcytosis. In addition, the interesting history of splenomegaly in childhood and the long-standing symptomless anemia should be noted. The anemia was resistant to therapy, including large amounts of iron and extrinsic factors.

The family of the patient could not be shown to have this blood disorder.

The patient's blood disorder differed from Mediterranean anemia (Cooley's erythroblastic anemia<sup>2</sup>) only in lacking erythroblasts in the circulating blood and in roentgenographic changes in the bones. The latter may well be related to bone-marrow hyperplasia in growing bone.

This condition differs from familial microcytic anemia<sup>3</sup> because of absence of the disorder in other members of the family and the absence of skull changes with roentgen-ray study. In addition, our patient had splenomegaly, a permanently elevated serum bilirubin and a more abnormal stained blood smear.

The disorder appears to be similar to some of the cases described by Wintrobe et al.<sup>1</sup> It is also similar to the condition described by Dameshek<sup>4</sup> as "target-cell anemia," except for the absence of bone changes.

### SUMMARY

A case of hypochromic microcytic anemia, associated with splenomegaly and subclinical jaundice resistant to therapy, is presented, and its differences from previously described idiopathic anemias summarized. The erythrocyte changes bear marked similarity to those found in Mediterranean anemia in children.

## NEW HAMPSHIRE MEDICAL SOCIETY

PROCEEDINGS OF THE ONE HUNDRED AND FIFTIETH  
ANNIVERSARY

House of Delegates, May 12, 13 and 14, 1941

THE House of Delegates convened at the Hotel Carpenter, Manchester, on May 12, 1941, at 7 30 p m, with Speaker Robert O Blood, of Concord, presiding

The following members answered the roll call

The President, *ex officio*  
 The Vice President, *ex officio*  
 The Secretary Treasurer, *ex-officio*  
 I yall A Middleton, Plymouth  
 Richard W Robinson, Laconia  
 Francis J C Dube, Center Ossipee  
 W J Paul Dye, Wolfeboro  
 Norris H Robertson, Keene  
 Walter T Taylor, Keene  
 Leslie K Sycamore, Hanover  
 Everett C Crippbell, Woodsville  
 Frederic P Lord, Hanover (alternate for Willard A Bates, Littleton)  
 Deering G Smith, Nashua  
 Henry O Smith, Hudson (alternate for Charles H Cutler, Peterboro)  
 Clarence E Dunbar, Manchester  
 George V Fiske, Manchester  
 George C Wilkins, Manchester (appointed as alternate for Luther A March, Nashua)  
 Warren H Butterfield, Concord  
 Charles H Parsons, Concord  
 Herbert B Messinger, Franklin (alternate for Robert J Graves, Concord)  
 Martha I Boger-Shattuck, Portsmouth  
 James Sanders, Rye  
 Frederick S Gray, Portsmouth  
 Edna Walck, Dover  
 Albert E Barcomb, Rochester  
 Henry C Sanders, Jr, Claremont  
 William M Prince, Newport

The Speaker declared a quorum present, and appointed the Credentials Committee as follows Drs Dunbar (chairman), Dube and H C Sanders, Jr Dr Dunbar reported that the credentials were in order

The Speaker appointed the Committee on Officers Reports as follows Drs D G Smith (chairman), Sycamore and Robertson He appointed the Committee on Memorials and Communications as follows Drs Parsons (chairman), Beruoin and Middleton To the Committee on Nominations he appointed Drs Robertson (chairman), Robinson, Dunbar, Gray and Walck

The secretary treasurer, Dr Carleton R Metcalf, presented his report

*Report of the Secretary Treasurer*

	<hr/>
Net receipts from annual meeting deposited 3/14/41	\$6,472.52 248.42
	<hr/>
	\$6,720.94

The Society is in good financial condition, with a balance of \$119.68 in the bank on January 5, 1941. The Benevolence Fund on the same date amounted to \$2944.00; of this amount the principal is \$2594.19, and the accrued income, \$349.81. During the past year we have received \$225.00 for this fund from the women's auxiliaries of the following counties:

Strafford	\$50.00
Coos	10.00
Merrimack	25.00
Rockingham	40.00
Hillsborough	100.00

We gave \$100.00 to Mr. Frank J. Sulloway as a retaining fee, and \$100.00 to the Auxiliary to cover, in part, the expenses of its meeting last May.

Two officers of the Society have died during the past year: Osmon H. Hubbard, of Keene, and Fred E. Clow, of Wolfeboro. Both were members of the Advisory Committee on Jurisprudence. Dr. Hubbard was a former president of the Society, and Dr. Clow a former speaker of the House of Delegates.

The President chose David W. Parker, of Manchester, for anniversary chairman and appointed Harry O. Cheslev, of Dover, to membership on the New England Medical Council. The value of the New England Medical Council seems to me highly questionable. It has not had a meeting for years, and two or three years ago when we tried to get the different New England states to hold a meeting, Massachusetts was the only state that responded. It seems rather a futile gesture to appoint members to the council annually.

A year ago the House of Delegates made the following recommendations, which have been carried out:

Fifty dollars was given to the Cancer Committee for its work.

The members of the Society were urged to accord moral and financial support to the National Physicians Committee for the Extension of Medical Service.

A Committee was appointed to co-operate with the University of New Hampshire in celebrating its seventy-fifth anniversary.

I requested the chairman of the Committee on Officers' Reports and the chairman of the Committee on Memorials and Communications to send to each delegate an agenda of important matters to be taken up by delegates at this meeting.

Two thousand dollars was sent to Dartmouth College for use of the Medical School.

I conveyed to our United States senators the resolutions of the Society pertaining to the Wagner Act.

I conducted a postal-card ballot concerning the elimination or retention of round-table conferences at our annual meetings. The results were as follows:

*Do you prefer to return to the former plan of having members read set papers?* Yes, 44. No, 129. No answer, 10.

*If we return to the former plan, will you be willing to write and read a paper?* Yes, 54. No, 57. No answer, 64.

*Prefer present plan but will write a paper if former plan adopted:* 26.

*Prefer former plan and will write a paper if former plan adopted:* 25.

*Prefer neither plan but will write paper if former plan adopted:* 3.

There has been very little important medical legislation in the present session of the Legislature. I have appeared before a committee only once, to oppose the Federal Narcotic Bill, which contains a great deal of red tape and which would compel the State, at considerable expense, to carry on the work that is now being adequately done by the federal government. The bill was defeated.

The State Board of Health has requested us to appoint a Committee on Public Health to confer with them from time to time on matters in which they wish the opinion of the Society.

I shall be glad to have you instruct me in regard to

the action that I should take concerning doctors who are now or who will be in the United States Army. Should they be continued as members of the Society without payment of dues or should they be dropped from the rolls?

The President and I have had several meetings with General Bowen in regard to Selective Service. General Bowen requested us to choose doctors in various parts of the State to carry on the work of examining the draftees. We selected 176 doctors, and I am happy to say that every one of them agreed to serve without pay.

CARLETON R. METCALF, *Secretary-Treasurer*

Dr. Metcalf added that several other things should be mentioned: first, a communication from the Hartford Accident and Indemnity Company to the effect that, effective May 1, 1941, the annual rate for malpractice liability insurance for members of the Society had been reduced from \$40.00 to \$37.50 for the standard coverage of \$5000 to \$15,000; secondly, that \$1000 had been transferred from the General Fund to the Benevolence Fund; and, thirdly, that the expenditure of \$150 for political work in Belknap County seemed justified to the officers of the Society.

The report was accepted and was reported on by Dr. D. G. Smith, of the Committee on Officers' Reports. Dr. Smith spoke of the fact that several committee chairmen had failed to forward their reports to his committee in time for copies to be sent to the delegates; after some discussion, it was the consensus of the delegates that the chairmen should observe more strictly the regulation requiring the filing of reports by April 15.

Dr. Smith recommended that Article XII of the constitution, relative to the New England Medical Council, be deleted. (Action on this proposed amendment will be taken in 1942.)

Dr. Smith recommended that a standing committee, the Committee on Public Health, be appointed; after considerable discussion it was voted to table the question until the following day.

Dr. Smith recommended that the dues of members on extended active duty with the military and naval services of the United States be remitted for that calendar year in any part of which they are on active duty; it was so voted.

Because of the amount of business to be transacted, it was voted to omit the reading of the councilors' reports.

### *Reports of Councilors*

#### BEKNAP COUNTY

The Belknap County Medical Society held six meetings from November to April inclusive. The meetings were very well attended, some members driving over fifty miles to attend. As usual a dinner was served at 6:15, followed

by the program. The Women's Auxiliary met at the same time and place.

The society has thirty-seven members.

C. S. ABBOTT

#### CARROLL COUNTY

The Carroll County Medical Society has held its meetings at Center Ossipee as usual. The Auxiliary has held its meetings at the same time and place.

Our numbers are small, since our membership comprises but sixteen names; however our spirit is excellent and our meetings well attended.

C. E. SMITH

#### CHESHIRE COUNTY

The Cheshire County Medical Society held two well-attended meetings during 1940. At each meeting outside speakers presented papers of interest. These papers were given in such a way that much discussion followed. Discussions always stimulate interest and add to the value of such gatherings.

Three new members have been added to the society during the past year. This addition, however, did not swell our membership, since we lost three members by death: Dr. Hubbard, of Keene; Dr. Goldsmith, of Winchester; and Dr. Sheldon, of Troy. Dr. Goldsmith and Dr. Sheldon were fairly recent members, but by Dr. Hubbard's death the society lost one of its oldest members. Though quiet and unassuming, Dr. Hubbard had the faculty of accomplishing whatever he undertook. His activities in county and state medicine were many—to mention but a few, he had been president of the county society, president of the New Hampshire Medical Society, president of the staff of the Elliot Community Hospital and state pathologist.

JOHN J. BROSNIHAN

#### COOS COUNTY

We had no fall meeting this year. Our annual meeting was held in Berlin on April 26, 1941. The guest speaker was Dr. Henry Faxon, from the Massachusetts General Hospital, who gave us a very interesting talk on the subject, "Diagnosis and Treatment of Common Peripheral Vascular Diseases."

The society voted to let the Farm Security Administration function in our county.

We have forty-one members now, having lost two by removal and one by death. On the whole, our society is in a healthy condition.

We feel the loss of Dr. Homer Marks, who died on April 11, 1941, following an accident.

RICHARD E. WILDER

#### GRAFTON COUNTY

The annual business meeting of the society was held at the Hitchcock Hospital, Hanover, on October 30, 1940. President Ezra A. Jones, of the New Hampshire Medical Society, and Deering G. Smith, chairman of the New Hampshire Committee on Medical Preparedness, were present and led in the discussion of problems of medical preparedness. Dr. R. C. Tanzer, of Hanover, presented an interesting paper, "Special Problems in Plastic Surgery."

The spring meeting was held at the Hitchcock Hospital, Hanover, on March 28, 1941. It was voted to ap-

prove the plan of the Metropolitan Casualty Insurance Company for group disability insurance for members of the society. A sound motion picture, "Conception and Contraception," furnished by the Ortho Products Company, was presented.

The society has contributed to the support of the National Physicians Committee and has also contributed an emergency medical kit to the Medical and Surgical Relief Committee for Britain.

ARTHUR W. BURNHAM

#### HILLSBOROUGH COUNTY

The Hillsborough County Medical Society has had two meetings since the last annual meeting of the New Hampshire Medical Society.

On October 29, 1940, we met at the Manchester Country Club and the meeting was presided over by Dr. J. S. Black, of Nashua. At that time, six new members were admitted to the society; since then, two have been lost by death. At the business meeting a very interesting talk was given by Dr. Deering Smith, the New Hampshire delegate to the American Medical Association, on the subject, "Medical Preparedness." This was followed by much discussion. Remarks were made by Dr. Ezra Jones, president of the New Hampshire Medical Society, calling to our attention the fact that 1941 was the one hundred and fiftieth anniversary of the New Hampshire Medical Society. After luncheon, a paper was presented by Dr. Lyman G. Richards, of Boston. The topic of Dr. Richards's interesting paper was "Practical Bronchoscopic Diagnosis and Therapy," illustrated. Another paper of interest was by Dr. Joe Vincent Meigs, of Boston, and was titled, "Symposium on Vaginal Bleeding: Amenorrhea, dysmenorrhea and abnormal bleeding."

Our spring meeting was held in conjunction with the New Hampshire Surgical Club at the Nashua Country Club on April 29, 1941, with over a hundred physicians attending; Dr. George T. Sheehan, president of the society, presided.

The scientific program of this meeting included surgical clinics at St. Joseph's and Memorial hospitals and papers on the following subjects: "The Treatment of Toxemias of Pregnancy," by Dr. Marion Fairfield; "Peritonitis," by Dr. Loren F. Richards; "Middle-Ear Infection," by Dr. Raymond Marcotte; and "Large Inguinal Rings as a Bar to Employment," by Dr. Richard Mulvanity. During the afternoon Dr. Joseph W. O'Connor, of Worcester, Massachusetts, presented a very interesting paper, "Spontaneous Rupture of the Uterus: Its diagnosis and treatment." He was followed by Dr. John M. Birnie, of Springfield, Massachusetts, who gave an excellent presentation on the subject, "Large Inguinal Rings and Potential Hernias." Both of these were discussed by members of the society and the club, and then followed a motion picture, "Vitamin B Deficiencies and Their Treatment," shown by E. R. Squibb and Company.

Of the 179 physicians in Hillsborough County, 140 are members of the Hillsborough County Medical Society. Several new members were admitted at this meeting. Four of our members, Dr. R. E. Fiske, Dr. G. J. Kapopoulos, Dr. R. M. Bremner and Dr. D. L. Hallisey, are on active duty with the National Guard. There are eight medical reserve officers in the county, of whom Dr. M. O. Goodman, Dr. P. R. Hamel, Dr. R. E. Lapointe and Dr. R. R. Rix are on active duty for a year.

The accident and health insurance plan which was proposed to our members at the last meeting and approved

by them has gone into effect, over half the eligible members taking out policies.

CLARENCE O. COBURN

#### MERRIMACK COUNTY

A summer meeting was held at Franklin at the Country Club on July 10, 1940. About twenty members attended. Dr. Levine, of Bristol and Concord, gave a paper on superstitions relating to medical treatment in the early New England period. A local county defense committee, consisting of Dr. McQuade, of Franklin, Dr. MacLean Gill, of Concord, and Dr. Warren Butterfield, of Concord, was elected.

At the fall meeting, held on October 2, 1940, at the Eagle Hotel, Dr. Deering G. Smith discussed the defense program and the part the medical profession will have in it.

On January 8, 1941, the following officers were elected: president, Dr. MacLean J. Gill; vice-president, Dr. Edward Putnam; secretary-treasurer, Dr. Warren Butterfield. Mr. Davis, of Nashua, and Manager L. F. Carter, of the Metropolitan Casualty Company, presented a plan for health and accident insurance for the members of the society. A motion was made and passed to accept this insurance plan and to authorize the committee of five to make the necessary arrangements.

On April 2, 1941, a noon meeting was held at the Eagle Hotel; about twenty-five were present. The Orthogynol Company presented a motion-picture film with sound track, "Studies in Human Fertility: Methods for the control of conception."

HENRY H. AMSDEN

#### ROCKINGHAM COUNTY

Rockingham County Medical Society has held two meetings during the past year, the spring meeting at the Portsmouth Hospital and the fall meeting at the Exeter Hospital.

At these meetings, cases were presented showing end results. At the fall meeting, a paper was read by Dr. Robert Zollinger, of Boston. At the spring meeting, Dr. Ezra Jones, of Manchester, talked on various difficulties in treating many types of fractures and Dr. A. Peters discussed the use of lipiodol in determining the patency of the fallopian tubes by x-ray. The meetings were very interesting, instructive and well attended.

HERBERT L. TAYLOR

#### STRAFFORD COUNTY

The Strafford County Medical Society has twenty-nine active members and six affiliate members. Two applications for membership were acted on at the April 30, 1941, meeting.

The annual meeting was held on October 30, 1940, at the City Hotel in Rochester. It was the one hundred and thirty-third meeting of this society and was attended by twenty-five members and one guest. Dr. Deering Smith, chairman of the State Committee on National Defense, spoke on the American Medical Association's plan to register all physicians in the United States and on their place in the national defense program. During the winter and early spring months, every physician in Strafford County was registered in accordance with this program.

Our spring meeting was held on April 30, 1941, at Simpson's Pavilion in Dover, with twenty-two members

and two guests present Dr Chester S. Keefer, of Boston, spoke, his subject being The Modern Treatment of Pneumonia. Considerable business was transacted, which included voting two new Rochester physicians to membership, voting Dr A. P. Richmond, formerly of Dover to honorary membership, appointing a committee to study the so-called Houston Plan, a vote against any change in the present Cancer Commission and telegrams of such action sent to the secretary of the New Hampshire Medical Society and to Winslow Osborne, chairman of the Committee on Revision of Statutes, State House, Concord presentation of Group Health and Accident Insurance for Physicians, which was favorably accepted. This was the most active meeting we have had for some time.

During the year 1940 one member was lost by death—Dr L. L. Gilman, of Rochester, who died on April 12, 1940, at the age of seventy-one. Dr Andrew J. Oberlander, formerly at New Hampshire University accepted a position with an insurance company and moved to Burlington Vermont. Dr L. H. Mendelson formerly of Dover, removed to Winchester. Dr Dean Wilder Dr Oberlander's successor at New Hampshire University went to Derry to become a general practitioner.

Dues of all the members were paid promptly and disbursed to the state society treasurer on February 6, 1941.

JOHN A. HUNTER

#### SULLIVAN COUNTY

The Sullivan County Medical Society held two meetings during the past year. The summer meeting was held at Seven Hearths, in Sunapee, and consisted of a luncheon followed by a scientific session, at which Dr Ralph E. Miller, of Hanover, talked on laboratory technique and the need of laboratory examinations in general practice, particularly stressing frequent blood sugar determination in the treatment of diabetes.

The winter meeting was held at Claremont. At this time officers were elected for 1941. The speaker was Dr George S. Amsden, of Alstead, who gave a very interesting and instructive talk on the neurologic patient. We had hoped to have our state society president at this meeting and were much disappointed that he could not attend.

We are pleased to report the Sullivan County Society in a very healthy condition.

EMERSON M. FITZGIB

Dr D. G. Smith then made his report as delegate to the American Medical Association.

#### *Report of the Delegate to the American Medical Association*

The ninety-first annual session of the American Medical Association, held in New York City, June 10-14, 1940, was the best attended medical meeting that has ever been held, the total registration being 12,864, more than 2500 greater than any previous session. Thirty-nine New Hampshire doctors were registered, and your delegate served as sergeant at arms at the meetings of the House of Delegates. The secretary reported the membership of the American Medical Association to be 116,266, an increase of 15,000 members in five years, which is proof of the solidarity of the medical profession. Dr Rock Sleyter, the president, remarked on how little the average doctor knows about the association and what it is doing. He recommended the training of speakers who could appear on the programs of the various county societies to bring

home to the doctors the activities and policies of the American Medical Association.

The House of Delegates recommended to all state medical societies that they hold conferences with the authorities of their state boards of health, with the view of limiting the type and extent of services offered by the laboratories of these organizations. Laboratory services by the state board of health laboratories should be confined to requests made by health officers and to those made by physicians whose patients find it difficult or impossible to pay the cost of laboratory services of this kind in the customary manner. In general, laboratories of the state boards of health should not provide services at taxpayers' expense to persons who are able to provide for themselves.

The by-laws were amended by creating a new section of the scientific assembly, the Section on Anesthesiology. It was also proposed to amend the constitution so that only doctors of medicine licensed to practice medicine and whose licenses are registered in the state or county in which they make application be accepted for full membership in the American Medical Association. The determination on the part of the Board of Trustees to use every effort and means to defend the American Medical Association against the charges that it is guilty of conspiracy and of violating antitrust laws received the wholehearted endorsement of the House of Delegates. New England was honored by the choice of Frank H. Lahey, of Boston as president elect.

Medical preparedness was the major topic discussed at the meetings of the House of Delegates. Colonel George C. Dunham submitted a tentative plan for the procurement of professional personnel for the Medical Corps of the United States Army in the event of a national emergency. This plan was prepared by the office of the Surgeon General of the United States Army and was endorsed in principle by the House of Delegates. The House of Delegates created the Committee on Medical Preparedness, which is to establish and maintain contact and suitable relationship with all governmental agencies concerned with the prevention of disease and the care of the sick, in both civil and military aspects, so as to make available at the earliest possible moment every facility that the American Medical Association can offer for the health and safety of American people and the maintenance of American democracy.

The president and secretary of the New Hampshire Medical Society were asked to recommend a chairman for this state. Following their recommendation, Dr Deering G. Smith was appointed New Hampshire chairman by the Committee on Medical Preparedness of the American Medical Association. Dr Smith chose Dr L. A. Jones and Dr Carleton R. Metcalf to serve with him on the state committee. On the suggestion of the state chairman, the president and secretary of each of the county societies appointed medical preparedness committees in their counties.

At the request of the Surgeons General of the United States Army, Navy and Public Health Service, a questionnaire was sent to every licensed physician in the United States in order to have an inventory of the doctors and their capabilities. The county medical preparedness committees have cooperated in getting doctors to complete these questionnaires and blanks have been returned for every doctor in this state. The information on these questionnaires has been copied onto punch cards so that it is possible by the use of the usual machines to pick out any special group of physicians.

The carrying out of the Selective Training and Service Act of 1940 necessitated the use of physicians as examining physicians of the draft boards and as members of the medical advisory boards. The president and secretary of the Society made recommendations of doctors to the Governor, who nominated the physicians for the President to appoint, and who appointed the members of the medical advisory boards.

It was found necessary to use some civilian physicians for the final examinations for the United States Army. Volunteers were asked to serve on the medical induction boards, and over thirty physicians answered this call.

Dr. Smith spoke on medical preparedness at a majority of the county medical meetings in the fall, has attended several conferences, and has directed this work in the State. Every effort is being made to provide for the medical care of the United States Army and at the same time to look after the needs of civilian hospitals and of cities and towns, especially to prevent the stripping of rural and isolated communities of their necessary medical personnel. Information has been sent to the Corps Area Surgeon as to which medical reserve officers may be spared for active duty at this time and which officers should remain at home to take care of the needs of the community or its hospitals. At the present time each county medical preparedness committee is making a similar report about the other physicians in its county. The names of physicians who are deemed essential for the medical staffs of hospitals and related institutions, health departments and medical schools are being listed, and also the names of physicians who are needed for full-time industrial practice and for the care of the civilian population.

Eight New Hampshire doctors are now in active federal service with the National Guard, and at least sixteen other doctors are now serving a year's active duty as medical reserve officers. The practices of these physicians and of physicians who will subsequently go into the military service should be protected, and the House of Delegates recommended to the constituent state and component county societies that they work out plans whereby the practice of physicians absent from their homes in the service of our military and naval forces be protected, and whereby some financial return from such practice be secured for the physicians so absent in the service. Your delegate recommends that this matter be referred for study and action to the Committee on Medical Economics.

It is suggested that a committee on medical preparedness be chosen by this society, so that no question of authority may arise when we are dealing with the state and federal governments.

Your delegate appreciates the excellent work that the examining physicians of the draft boards and the members of the medical advisory boards have been doing. He has had the full co-operation of all the doctors of the State, and especially thanks the members of the medical preparedness committees for their assistance.

DEERING G. SMITH

As chairman of the Committee on Officers' Reports, Dr. D. G. Smith recommended that the part of his report dealing with medical defense should be read at the general meeting of the Society; it was so voted. After some discussion, the recommendation that the Committee on Public Health be instructed to study the problem rel-

ative to the State Laboratory as a real competitor of the clinical pathologists was laid on the table indefinitely. Dr. Smith's recommendation that the matter of protection for the practices of members who left the State because of military or naval service be referred to the Committee on Medical Economics for study and action was approved, as was the suggestion that a committee on medical preparedness be created, the suggestion being made that the New Hampshire Committee on Medical Preparedness of the American Medical Association constitute this new committee of the Society.

Dr. Woodman then presented the report of the Committee on Amendments to the Constitution and By-Laws.

### *Report of the Committee on Amendments to the Constitution and By-Laws*

The Committee on Amendments to the Constitution and By-Laws met on March 31, 1941, and compared our constitution and by-laws with those of the American Medical Association. Owing to the excellent work of Dr. H. O. Smith and his committee, we find no discrepancies. We make the following recommendations:

1. It is recommended that, in Chapter VIII, Section 1, of the by-laws, the Nominating Committee be stricken from the list of standing committees. This committee is a special committee appointed for a special purpose and is provided for in Chapter V, Section 2, of the by-laws.

2. It is recommended that, in view of the above, Chapter VIII, Section 2, of the by-laws be stricken out entirely.

3. It is recommended that the list of standing committees shall include a committee on child welfare and maternal health.

4. It is recommended that a section be added to Chapter VIII defining the Committee on Child Welfare and Maternal Health as a committee consisting of three members whose duties it shall be to investigate the condition of child welfare and maternal health throughout the State, to report to the Society the cause of maternal and infant mortality and morbidity and to recommend any course of treatment or method of procedure that would improve such existing conditions.

5. It is recommended that each county society shall compare its constitution and by-laws with those of the state society and see that no conflict exists.

JAMES B. WOODMAN  
CHESTER L. SMART  
FREDERICK S. GRAY

Dr. D. G. Smith, acting for the Committee on Officers' Reports, approved the recommendations and proposed the following changes in the by-laws:

1. Chapter VIII, Section 1: strike out "A Committee on Nominations."

2 Chapter VIII strike out Section 2

3 Chapter VIII, Section 1 add a Committee on Maternal Health and Infant Welfare after a Committee on Medical Education and Hospitals

4 Chapter VIII renumber Sections 3 to 12 inclusive, making Section 3 Section 2 and so forth

5 Chapter VIII add a new section Section 17 as follows

The Committee on Maternal Health and Infant Welfare shall consist of three members whose duties it shall be to investigate the condition of maternal health and infant welfare throughout the State and to report to the Society the causes of maternal and infant mortality and morbidity and to recommend any course of treatment or method of procedure which would improve such existing conditions

The committee also recommended that, if the amendments were adopted, the Committee on Maternity and Infancy should be abolished. Since no action could be taken, the proposed changes were tabled until the next meeting. However, it was voted that it was the sense of the meeting for the Committee on Maternal Health and Infant Welfare and the Committee on Child Health to be standing rather than special committees.

Dr Wilkins then presented the report of the Committee on the Control of Cancer

### *Report of the Committee on the Control of Cancer*

During the past year your committee has sent out three letters to every physician in New Hampshire. These one page letters have dealt with three phases of cancer control.

The first was a quotation on cancer education for the physician, which was written by Dr C C Little, the director of the American Society for the Control of Cancer. This letter dealt with the accomplishments in my education that had been directed toward informing the public of the danger signals of cancer and an attack on fear of the disease. The unreasonable fear of cancer and discussion of it have been controlled to a considerable degree and the education of the public has reached a point where there is definite need for further medical education although this need varies in different states and communities.

The second letter dealt with the necessity of examining patients who have abnormal flowing even though the flowing is present at the time of the visit to the doctor. Too many patients have remained away too long a time when told to return when flowing ceased. Physicians were also urged to encourage women to have a vaginal examination between the ages of thirty five and forty and to advise cauterization and repair of cervical erosions when discovered. The importance of periodic examinations was also stressed in this letter.

In the last letter, yearly physical examination was stressed more fully, and certain diagnostic procedures were discussed that should be observed in making an examination. Your committee believes that if these rules were followed in all physical examinations very few early cancers would be overlooked in the patients thus examined.

Here in New Hampshire we believe that the medical profession is constantly growing more alert in recognizing conditions that may indicate the possibility of cancer and reports from the various diagnostic clinics in the State bear out this assumption since more and more physicians

are sending patients to the clinics for assistance in making definite diagnoses. The important educational work of the Women's Field Army continues, and through its efforts, hundreds of women have become interested in cancer control and through their efforts thousands of pamphlets giving information in simple language have been distributed to homes throughout the State. These women as a group have many times praised the assistance and co-operation of the physicians in their communities.

Last July the Women's Field Army donated funds for the purchase of about six hundred copies of the book *Cancer Manual for Practitioners*. One of these volumes was sent to every member of the Society. We assume that every physician receiving this most informative book appreciated it although the Women's Field Army had only ten letters of thanks.

New Hampshire is a small state, most of our physicians are intelligent and alert and the New Hampshire Medical Society is a fairly compact group hence your committee believes that there is no reason why the medical profession of this state should not lead other states in its ability to recognize cancer early and see that patients receive early and competent treatment. Your committee will gratefully receive any suggestions of further means and methods by which our educational efforts can be improved.

The committee has spent \$42.57 for printing and postage the balance of \$7.43 having been returned to the Treasurer. We request another appropriation of \$50 for the coming year.

GEORGE C. WILKINS

On the recommendation of Dr D G Smith, of the Committee on Officers' Reports, the appropriation of \$50 for the work of the cancer committee and the sending by the Secretary of a letter to the Women's Field Army expressing gratitude for the forwarding of copies of the cancer manual to all members of the Society were approved.

The report of the Committee on Medical Economics was read by the chairman, Dr Robinson.

### *Report of the Committee on Medical Economics*

The Committee on Medical Economics has continued the activities reported at the last annual meeting and presents the following report on the problems it has considered.

*Medical Care for Clients of the Farm Security Administration*—This program was in effect in Grafton and Cheshire counties for the full year of 1940. It appears to have worked out in general to the satisfaction of both the patients and the physicians concerned. All bills submitted by the participating physicians during the year were paid in full. Repayment of loans made to clients by the Farm Security Administration was in the neighborhood of 90 per cent, a fact indicating that in the majority of instances the program is fulfilling its original purpose of maintaining the self-sufficiency of the participating clients and has not degenerated into a government subsidy. The plan is being continued in Grafton and Cheshire counties for the year 1941. The prospects for successful operation are somewhat more uncertain this year since shifting economic conditions are causing migration of labor from farm to industry and the number of families participating will probably be smaller than that of last year. Your committee will continue its observation of the

operation of the program, and makes no specific recommendations at the present time.

*National Physicians Committee for the Extension of Medical Service.* This committee has done valuable and effective work during the past year in interpreting the aims and ideals of the medical profession to the public, and in combating undesirable trends toward government interference in the practice of medicine. Since it is a vital concern of physicians today that the public be educated to a sympathetic understanding of their position, and since the National Physicians Committee appears to be an effective and ethical agency for the attainment of this purpose, your committee recommends the continued moral and financial support of the committee, both by physicians individually and by the county and state societies. Specifically, it is recommended that the state and county societies make use of the news releases furnished by the National Physicians Committee for insertion in local newspapers.

*Group Sickness Insurance.* Your committee has continued its study of various plans now in effect for group insurance against the costs of medical care. It has considered the advisability of a fact-finding survey of conditions in New Hampshire, but has concluded that it would be useless to conduct such a survey at the present time, in the face of rapidly changing economic conditions. Furthermore, it is the opinion of your committee that with the expanding opportunities for employment that exist at present and will probably continue to exist for some time to come the need for group insurance against the costs of sickness is less acute than it has been in the recent past. Your committee believes, however, that the New Hampshire Medical Society should be prepared to introduce such a program if and when it should seem desirable in the future. Since a prerequisite of any such program would be the passing of an enabling act by the Legislature, it is recommended that the Committee on Public Relations or the Committee on Medical Economics be instructed to consult with Attorney Sulloway with the purpose of drawing up such a bill for later submission to the Legislature.

RICHARD W. ROBINSON, *Chairman*  
CLARENCE E. DUNBAR  
LESLIE K. SYCAMORE

Dr. D. G. Smith, for the Committee on Officers' Reports, expressed gratification that the plan for the medical care for clients of the Farm Security Administration was in successful operation, approved the work of the National Physicians Committee for the Extension of Medical Service, and urged that the news releases of the latter organization be used by the secretaries of all state and county medical societies. He recommended that the Committee on Public Relations and the Committee on Medical Economics consult with Mr. Sulloway relative to enabling legislation for group insurance against the costs of medical care and report back to the House of Delegates at its next annual meeting; after some discussion, the motion was passed.

The report of the Committee on Medical Education and Hospitals was then presented.

## *Report of the Committee on Medical Education and Hospitals*

### POSTGRADUATE MEDICAL EDUCATION

The New England Postgraduate Assembly will hold its fourth annual session in October on dates which will not be in conflict with any state medical society meeting or other major medical function. On the recommendation of your representative, the emphasis in the program will be from the viewpoint of the general practitioner.

A preliminary program will be issued this spring under the direction of the co-chairmen, Drs. Chester S. Keefer and Joseph H. Pratt, for medicine, and Drs. Howard M. Clute and William E. Ladd, for surgery. The success of the previous programs is a guarantee of the value of the next. An attendance of eight hundred, a modest expectation from the five states, will assure the necessary income for expenses, thus obviating underwriting by the Society. Each member should begin now to formulate plans permitting attendance.

At the fourth annual session of the Associated State Postgraduate Committees held in New York City on June 12, 1940, the new chairman, Dr. Frank R. Ober, of Boston, appointed a committee to study a proposed national registry of postgraduate instructors and meetings. The New England member is Dr. Frederick T. Hill, of Waterville, Maine. In the meantime an interstate mailing list has been established, permitting a nation-wide exchange of information, which is especially important in these days of constant scrutiny from without and within that call for continual alertness in how to provide the best grade of medical service for the protection of public health in the national interest, in which postgraduate instruction is a most significant factor.

### COMMONWEALTH FUND FELLOWSHIPS

Postgraduate medical education in our own society has been significantly influenced in the past half decade by the fellowships provided by the Commonwealth Fund. It seems appropriate at this time to present a summary of these because of their importance as historical evidence of trends in the State, and because the bare numbers might appear to constitute something of a challenge to a certain age group in the Society when considered in the light of the fact that almost without exception the applicants who have been out of medical school five years and who have not been more than forty-five years of age have received awards within the limits of the fellowships available for any particular year.

It might be considered, on the other hand, from the basis of the same bare numbers that the Society has made a very respectable showing. It would be impossible to determine exactly how many fellowships under their specifications the directors of the Commonwealth Fund might have awarded during the period assuming an unlimited supply, but a statistical study discloses that somewhere between one fifth and one third of all those who might have been eligible did receive fellowships.

Sixty fellowships were awarded to thirty-seven of forty-two applicants; twenty-one fellowships were single, while ten awards were double. Five physicians received three grants, and one received four. Over half (thirty-three) were in medicine, ten in obstetrics, eight in pediatrics, seven in surgery, and two in x-ray. Two took medicine twice, and one each repeated pediatrics and x-ray.

In 1936 there were eight, in 1937 fourteen, in both 1938

and 1939 eleven, and in 1940 sixteen applications, in contrast with six for 1941. Each year new eligibility comes into existence and older practitioners are still considered on the basis of their individual qualifications. The directors of the Commonwealth Fund have shown a broad and most intelligent understanding of the problems of practice in the State, and it is to be hoped that our members will express their appreciation by continuing to take advantage

of this opportunity of maintaining to an increasing degree a high level of professional competency.

JOHN P. BOWLER, *Chairman*

JAMES W. JAMESON

HERBERT L. TAYLOR

(To be continued)

## MEDICAL PROGRESS

### THE TREATMENT OF DEGENERATIVE JOINT DISEASE\*

CHARLES L. SHORT, M.D.,† AND WALTER BAUER, M.D.‡

BOSTON

AS WILL be noted by the title, we prefer the term, "degenerative joint disease," to any of the more commonly used synonyms: hypertrophic arthritis, osteoarthritis or senescent arthritis. Our reasons for this choice are, first, because it is now generally agreed that degeneration of the articular cartilage is the primary pathologic change<sup>1-15</sup> and, secondly, because true arthritis, which suggests inflammation and even infection, is very rarely present.

Degenerative joint disease is without doubt the commonest articular disorder. All persons beyond the second decade of life, although they may not complain of skeletal symptoms, exhibit anatomic alterations in their joints similar to the pathologic changes observed in this disease. The agent responsible for this articular lesion has a scope of unusual width, as indicated by the facts that many animal species<sup>4, 8, 12</sup> in dissimilar geographic locations and persons of both sexes are affected, and that not only the articular coverings but also the hyaline cartilage in various sites of the organism participate in the characteristic changes. Although sequelae identical to degenerative joint disease may supervene on the subjection of articular cartilage to a great variety of pathologic influences,—such as trauma, disturbed joint mechanisms and inflammatory joint disease,—there remain a very large number of cases of this disease in which no such factor appears to have been operative. Regardless of etiology, however, two fundamental considerations apply to every example of degenerative joint disease. One is the disadvantageous biologic position of the articular cartilage when it meets with injury; this is evident, anatomically, in the paucity of its cellular constituents and in its remoteness from blood supply and, physiologically, in its low respiratory rate and in its extremely limited faculty of autogenous repair.<sup>16</sup> The other concerns the effect of mechanical stress and strain incident to joint function on a tissue whose specific means of resistance to such use has been depleted. It is this second group of forces that plays the dominant role in the localization and progression of the arthropathy to the late and conspicuously deforming changes. The most constantly observed correlative to the so-called "primary form" of degenerative joint disease is increasing age. This has been well demonstrated in a recent report.<sup>15</sup> From this study, it is apparent that further knowledge concerning the cause and prevention of this articular lesion depends on precise data concerning the factors that govern maturation, maintenance and senescence of hyaline cartilage and other mesenchymal tissue. The best chance of obtaining this much-needed information resides in the development of better staining technics, the combination of microscopic observations and histochemical methods, and studies in tissue metabolism.

Those who have the misfortune to acquire pain and disability as a result of their degenerative joint-disease changes can be divided into two groups. In the first group, which might be termed the "primary or endogenous type," a factor as yet unrecognized is at work. In the remainder, which we may call the "secondary or exogenous type," long-continued trauma is the agent that oftentimes favors the development or acceleration of hyaline-cartilage degeneration. The various agents that may be operative and a knowledge of which is of value in reference to the

\*All articles in this series will be published in book form; the current volume is *Medical Progress: Annual, 1940* (Springfield, Illinois, Charles C. Thomas Company, 1941. \$4.00).

†From the Medical Clinic, Massachusetts General Hospital, the Department of Medicine, Harvard Medical School, and the Massachusetts Department of Public Health.

This is Publication Number 54 of the Robert W. Lovett Memorial for the Study of Crippling Disease, Harvard Medical School.

The expenses of this investigation were defrayed, in a large part, by a grant from the Commonwealth Fund, New York City.

‡Assistant in medicine, Harvard Medical School, assistant physician, Massachusetts General Hospital.

Associate professor in medicine, Harvard Medical School; physician, Massachusetts General Hospital.

treatment and to the prophylaxis of this condition are as follows: long-continued trauma, such as that in occupations demanding persistent use of one or more joints and that in obesity, in which the weight-bearing joints are subjected to unusual strain; static deformities resulting from severely pronated feet, knock-knees or bowlegs, poor posture (with obesity often a factor), fractures healing with malalignment, displaced patellas, incompletely healed sprains or unreduced dislocations or diseases of the epiphysis; and intra-articular disease, previous or present, which is the result of trauma (including osteochondritis dissecans, internal derangements of the knee joint, fractures into the joint and so forth), sepsis (joint infections due to the gonococcus, pyogenic organisms and so forth), gouty arthritis or rheumatoid arthritis.

It is thus apparent that degenerative joint disease may follow many types of articular injury and may often represent the end stage of other types of arthritis. Accordingly, the physician should not be satisfied with a clinical or roentgenologic diagnosis of this condition without first ascertaining whether one of the above-mentioned factors is of causative importance. Furthermore, he must make certain that the degenerative changes are actually responsible for the patient's symptoms, and that they are not merely a coincidental finding.

The onset of degenerative joint disease is usually gradual and the course chronic. Differentiation from the various acute and chronic arthritides is rarely difficult. As previously pointed out,<sup>17</sup> it is of extreme therapeutic and prognostic value to distinguish degenerative joint disease from rheumatoid arthritis. Patients showing evidence of both diseases should not be given the diagnosis of mixed arthritis. It is the physician's duty to decide whether the two diseases occupy a causative or a coincidental relation.

Since articular cartilage, because of its physiologic limitations, has a limited ability to repair itself, anatomic cure of degenerative joint disease is not possible. On the other hand, treatment directed toward the correction of causative or accelerating factors (if present and reversible) will arrest the progress of the disease and, in conjunction with simple measures to be described, will relieve the patient's symptoms.

Articular cartilage itself is insensitive. The pain in degenerative joint disease is therefore due to secondary changes, including muscle spasm caused by mechanical strain, loose bodies, secondary inflammation of fibrous tissue or bursae and elevation of the periosteum from the marginal overgrowth of cartilage and bone. The first three may be relieved by treatment, notably rest and re-

moval of irritating factors, and the last tends to subside when proliferation of cartilage ceases and calcification takes place. The most easily observed example of this process is seen in degenerative disease of the terminal phalangeal joints (Heberden's nodes), which often begins as a tender painful swelling that, in the course of a few months, becomes ossified and relatively painless. This tendency to self-limitation must be recognized in the evaluation of any form of therapy and has undoubtedly led to false claims of success from methods that rest on neither a theoretical nor a clinical basis; these include removal of foci of infection, vaccines, dietary regulation (with the exception of reduction diets) and endocrine therapy. In spite of many claims to the contrary, critical evaluation of present evidence is entirely against an infectious, metabolic or endocrine etiology for degenerative joint disease.<sup>11</sup>

One of us (W. B.<sup>17</sup>) has stressed elsewhere the necessity for a careful distinction between degenerative joint disease and rheumatoid arthritis. Once the physician is sure of his ground, the first essential step is to explain the nature of the condition to the patient, thus dispelling the fear of crippling and disability that has undoubtedly arisen in the latter's mind and has been fostered by the comments of his associates. For this reason, it is better to avoid the use of the term, "arthritis," altogether, on account of its gloomy connotation and to stress the favorable prognosis possible for the preservation of function and the relief of pain.

In brief, the principles of treatment of degenerative joint disease consist in reassuring the patient and explaining to him the nature of the disease, correcting responsible factors, if present, and affording symptomatic relief, so far as possible. Since it is often impossible in a given case to separate symptomatic measures from those that have a more direct effect on the progress of the disease, no attempt will be made to do so in the following detailed consideration of treatment.

## METHODS OF TREATMENT

### *Correction of Contributing Factors*

Once the diagnosis of degenerative joint disease has been made and its nature and prognosis explained to the patient, the physician's next consideration should be to decide whether any irritating or accelerating factors can be removed or ameliorated. As a check, the previously listed contributing factors should be consulted. If occupational trauma is still going on, the patient may be advised to change or modify his job. Obesity obviously calls for weight reduction, which is dis-

discussed below. Foot strain and poor posture suggest the use of supporting plates, belts and corsets, and the strengthening of flabby muscles by exercise. The treatment of other static deformities usually requires orthopedic consultation. Intra-articular disease of a traumatic nature may demand surgery. If an infectious arthritis plays a causative role and is still active, specific treatment should be instituted at once.

### *Diet*

None of the special diets that have been loosely applied to various forms of chronic arthritis are indicated in degenerative joint disease.<sup>18</sup> Protein, whether or not in the form of red meat, need not be cut down on account of the joint symptoms. Carbohydrates should be limited only if necessary to reduce weight. Whether or not the diet is "rough" depends on the patient's needs in regard to intestinal activity, diverticulosis and so forth. So-called "acid fruits and vegetables" bear no known relation to the degenerative process. From the nature of the pathogenesis of the disease, as described above, it is difficult to see how diet can play a direct role. Many claims for the successful use of certain diets undoubtedly depend on the spontaneous subsidence of periosteal irritation from encroaching marginal osteophytes. In short, the only known value of dietary regulation in degenerative joint disease lies in the field of weight reduction.

We have mentioned above that obesity may be a precipitating or accelerating factor in degenerative joint disease. Conversely, weight reduction will often relieve symptoms to a striking degree. In markedly obese patients, the indications are obvious, but relief is often gained by the loss of 10 to 20 pounds in patients only slightly over weight. It is of advantage to have the patient lose the first 10 or 20 pounds rather rapidly so that he may be encouraged to persevere from both the evidence of the scales and his less painful joints. The most striking benefit from weight reduction is in degenerative joint disease of the knees, which occurs in overweight women at or about the time of the menopause.

### *Climate*

The symptoms of degenerative joint disease may frequently be brought out by exposure to dampness or cold. For this reason, it is wise to caution the patient against such exposure and to insist on warm clothing when necessary, including gloves for patients with Heberden's nodes and long underwear for those with knee involvement. If practicable for those living in northern latitudes, much discomfort and even exacerbations

may be avoided by migration to a warm, dry climate during the winter season.

### *Drug Therapy*

No specific drugs are known that will alter the course or permanently do away with the symptoms of degenerative joint disease. None of the recently introduced so-called "specifics" for the treatment of arthritis have proved efficacious when tested under controlled conditions; these include gold salts, sulfur and massive doses of vitamin D.

Analgesics are of real value, but should not be used to the avoidance of rest, correction of irritating factors and other measures of proved worth. Aspirin, in regular dosage of 10 gr (0.6 gm) every three or four hours, is effective and inexpensive. Five grains (0.3 gm) of phenacetin or  $\frac{1}{4}$  to  $\frac{1}{2}$  gr. (0.015 to 0.03 gm) of codeine may be added to each dose of aspirin, if necessary. Compounds containing amidopyrine or cinchophen had best be avoided owing to the possibility of rarely occurring but serious toxicity. If morphine is needed, the physician should be suspicious that some other serious condition is also present, notably metastatic cancer.

Potassium iodide has long enjoyed a favorable reputation in the treatment of degenerative joint disease, but in our experience no benefit has been derived from the use of this drug that could not be ascribed to other measures or to the natural course of the disease.

The use of small doses of thyroid is permissible to increase metabolism and thus aid in combating obesity, but no specific effect has been proved from the use of this drug or other endocrine preparations. Of course, if myxedema is present in a patient with degenerative joint disease, the symptoms may be aggravated. In such cases, the use of thyroid is indicated. Similarly, if the patient is a woman with menopausal symptoms, replacement therapy with estrogenic material may be helpful, but no direct effect on the joint disease can be expected.

### *Rest*

Hospitalization is rarely necessary for patients with degenerative joint disease. Diagnosis can usually be made in the office with the benefit of a careful anamnesis and examination, in addition to roentgenograms of representative joints and routine examination of the blood and urine, with the occasional aid of the blood sedimentation rate. In a few patients, symptoms due to traumatic synovitis with effusion are sufficiently acute to require hospital care. A few others, of course, require hospitalization because of necessary surgery. The majority of patients can benefit by

rest at home according to the directions of the physician, often without interfering with housewifely duties or means of livelihood. The prescription of rest should be definite and included in the written directions, which are of great advantage in the management of a patient with chronic joint disease. It is obvious that relief of strain to the weight-bearing joints, which are the usual sites of degenerative joint disease, can be gained by a sitting or preferably reclining position for certain intervals during the day. The amount of rest prescribed varies with the severity of symptoms and may be gauged by trial, the relief of pain being the criterion. A good start may often be made by getting the patient off his feet for a week or two, followed by rest periods for one or two hours during the day. If work must be carried out, the patient can rest in the noon hour and at home before the evening meal. Finally, the amount of rest prescribed must be tempered by two considerations. In the first place, the patient must not believe that he is a permanently crippled invalid, cut off from his usual occupations and hobbies. At every point, the rationale of treatment must be explained, and the relatively good prognosis emphasized. A second consideration is that, in common with other forms of articular disease, the joints tend to become stiff and painful if kept in one position too long.

In addition to rest for the patient as a whole, the involved joints may acquire protection from strain by the use of certain advantageous positions or mechanical supports. For the cervical spine, periods of rest in a supine position, with no pillow or a low one, are of benefit. For severer symptoms, a Thomas collar or head traction is necessary. Similarly, for involvement of the lumbar and sacroiliac articulations, the patient should lie on the back with the knees and hips flexed during rest periods. A hard mattress should be employed, and boards may be placed between mattress and spring. When the patient is up and about, strain to the spinal and sacroiliac joints may be avoided by a corset—a brace is rarely necessary. If the patient drives a car, he should be able to reach the pedals readily with the knees flexed; if necessary the seat should be moved forward or a pillow should be placed behind his back. Painful hips may be relieved for a time by rest in bed, with traction on the leg or the use of a spica of plaster or leather. Elastic bandages or, better, a laced, part-leather, part-elastic kneecap takes from the knees much of the stress and strain of walking. Crutches allow the patient to be ambulatory, yet take the strain off a painful hip or knee. If the feet are involved, usually only in the secondary type of degenerative

joint disease, support and correction of faulty mechanics can be gained by the use of heel lifts and footplates. The aid of the orthopedist can be sought with advantage in planning these measures for the care of individually involved joints.

### *Physical Therapy*

Symptomatic relief, one of the chief aims of therapy in degenerative joint disease, can be aided by physical therapy in the form of heat, massage and graded exercises. The mechanism of relief by the use of heat is thought to be increased blood flow, although there is no evidence that the circulation to joint tissue is impaired in this disease. Simple methods of providing heat to the joints are perfectly satisfactory and have the added advantage that they can be applied several times daily in the home. These methods include the use of hot packs, hot baths and an inexpensive electric-lamp baker. Diathermy and other electric machines using short-wave modalities for heating the deeper tissues are no more effective than the simple methods. The physician should give definite directions to the patient concerning the frequency and duration of treatments. In general, heat may be applied for periods of not over fifteen minutes, two or three times daily. A state of chronic passive congestion and tissue hypersensitivity can be induced by overenthusiastic baking. Gentle kneading or light stroking massage of the muscles surrounding affected joints can be applied following the administration of heat. Heavy massage or massage over the joint itself provides a harmful form of trauma, which may increase the patient's symptoms. It is therefore essential that the physician give exact directions for this method of treatment, whether it is administered by a member of the family or a trained physical therapist.

### *Exercise*

Exercise, like rest, can be divided into that of the patient as a whole and that of the involved joints. In general, although a moderate amount may be necessary for weight reduction, exercise should be prescribed with caution. The patient should be informed that in this disease of the joints, activity is not necessary to prevent ankylosis, and overexercise may bear a definite possibility of harm. Frequently, pursuit of the patient's usual occupation will be all that the joints can stand. Violent sports should be avoided, especially those involving maximal use of an affected joint. Postural exercises, which are important to relieve weight-bearing joints of unnecessary strain, should be increased gradually—never beyond the boundary of pain. The exercise program for

strengthening the muscles that control the affected joints is much more important than the use of heat or massage. So long as the joint is inflamed and the muscles that control it are fatigued, they should receive complete rest. When spasm and inflammation have subsided, carefully graded muscle-setting exercises are begun and are persisted in daily until satisfactory power has been regained.

### *Psychotherapy*

We have already alluded to the value of reassuring the patient and explaining to him the nature of degenerative joint disease. If freed from fear of crippling, the patient often bears with equanimity the occasional aches and pains that treatment fails to relieve. Other patients, especially those complaining of undue fatigability, have a lowered threshold of sensibility, which accentuates symptoms that might be borne without complaint by more stoical persons. In such cases, the lessening of domestic or business cares, vacations with change of scene, and the search for and eradication of disturbing elements in the environment are all important in securing a satisfactory therapeutic result. For these patients, regular doses of a mild sedative, such as  $\frac{1}{4}$  gr. (0.015 gm.) phenobarbital after meals and at bedtime, may be more helpful than the use of analgesics.

### *Special Types of Degenerative Joint Disease*

*Heberden's nodes.* Degenerative joint disease of the terminal joints of the fingers is probably the commonest type seen in general practice. Rheumatoid arthritis can usually be readily distinguished, even without the aid of x-ray study and sedimentation rate; one should bear in mind, of course, that the two diseases may be present in the same patient in an unrelated form. It must also be remembered that the process may spread to the proximal joints in 10 to 20 per cent of the cases, or even rarely begin there. Acute cases, with marked tenderness, pain and occasionally fluctuation, must not be confused with acute gouty arthritis or sepsis. This condition is commoner in women than in men, and usually appears around the age of fifty. Younger patients with Heberden's nodes often give a history of premature development of the nodes in other members of the family. There is no specific treatment for this benign form of degenerative joint disease. The patient is more comfortable if the hands are kept warm and if trauma to them is avoided. The important thing is to explain the situation to the patient, who usually fears the worst, and assure him that he is not going to develop a crippling

disease and that the nodes, if acute, will subside in the course of a few months, whether treated or not.

*Temporomandibular involvement.* As recently described by Costen,<sup>19</sup> a variety of symptoms may result from degenerative disease of the temporomandibular joint, caused by loss of molar support or by malocclusion. These complaints include otologic symptoms (deafness, tinnitus, pain, dizziness and nystagmus), headache (occipital and vertical), herpes of the external auditory canal and buccal mucosa, and burning or dryness of the mouth and tongue. Roentgenograms may show loss of substance of the head of the condyle anteriorly and of the articular eminence. The insertion of cork disks between the molars may give temporary relief and may serve as a therapeutic test. Permanent relief of symptoms belongs to the sphere of dentistry.

*Morbus coxae senilis.* The treatment of degenerative disease of the hip joint, morbus coxae senilis, calls for an individually designed program for each case.<sup>20</sup> If there is flexion-adduction deformity, a period of complete bed rest, with adhesive traction of the leg, may be necessary. Heat and massage, as described above, should be given daily. When the muscle spasm has subsided, carefully graded exercises for the hip abductors and extensors (the gluteus medius and maximus muscles) should be prescribed and followed over a prolonged period. Four to ten slow voluntary contractions or so called "sets" of each muscle group at one sitting are repeated two or three times daily unless there is evidence of strain or fatigue. Unilateral hip disease may be protected from the strain of weight bearing by crutches. In some cases, restriction of motion by means of a leather or elastic knitted hip spica gives great relief. If there is apparent shortening of the leg due to fixed adduction contracture, the heel of the shoe should be raised sufficiently to compensate for the apparent inequality of leg length.

This is the one form of degenerative joint disease that may lead to actual crippling in spite of the conservative measures described above. Orthopedic consultation is in order for such cases to determine the advisability and type of operation. In an occasional patient, reestablishment of proper weight bearing lines and improvement of function may be gained by osteotomy of the femur. In severe cases, help can be given by a plastic operation on the anterior wall of the acetabulum<sup>21</sup> or, better, by means of a vitallium-cup arthroplasty.<sup>22</sup> In the hands of the originator,<sup>21</sup> these operations have been extremely successful in relieving pain and increasing the range of joint motion in

severe, incapacitating cases. Such an operation can be applied equally well to young patients with degenerative changes secondary to a slipping femoral epiphysis, Legg-Perthes disease and intra-pelvic protrusion of the acetabulum.

### Surgery

There are few indications for surgery in the treatment of degenerative joint disease, except for those already mentioned. One is the removal of loose bodies or so-called "mice" from the knee joint if pain, locking or secondary inflammation is caused thereby. Conservative treatment should be given a trial, but if incapacitating symptoms persist and the loose bodies are demonstrable by examination or roentgenograms, removal should be carried out without delay, since the degenerative process may be hastened by their presence.

Acute traumatic effusions usually subside with rest and splinting; if they persist, aspiration should be done.

### PROPHYLAXIS

Measures to prevent the development of degenerative joint disease or the acceleration of its course, once present, should be obvious to the reader on consulting the list of contributing factors already given. Such measures fall properly into the field of preventive medicine, and constitute one of the responsibilities of both family physician and specialist. In handling fractures and sprains, diseases of the epiphysis, rickets, infantile paralysis and so forth, the physician must bear in mind the possibility of premature development of degenerative joint disease if the joints are left subject to unusual strain. Static deformities and postural defects should be corrected as speedily and as completely as possible. Obesity, especially in those approaching middle age, is hazardous to the well-being of the joints, as well as of the other bodily systems. Repeated joint trauma, whether occupa-

tional or recreational, should be advised against. Finally, in a patient with any form of arthritis, the possibility of secondary degenerative changes must always be kept in mind and guarded against, especially if the movements of weight-bearing joints tend to become limited in a position of mechanical strain.

**CASE RECORDS OF THE  
MASSACHUSETTS GENERAL HOSPITAL**ANTE-MORTEM AND POST-MORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor***CASE 27301****PRESENTATION OF CASE**

A thirty-seven-year-old housewife entered the hospital with the complaint of joint pains.

About eleven years before entry, the patient began having mild attacks of pain in the shoulders and hands, which recurred every spring and lasted about two weeks. These attacks were relieved by salicylates and applications of heat. Three years later, her tonsils were removed for this condition. The following year, she developed a painful swollen ankle, and the condition soon spread to most of her other joints. Since then, she had had intermittent joint pains varying in intensity from time to time and usually aggravated by cold weather. The pain was not severe enough to keep her from doing her housework. Three years before entry, she developed a cough, with substernal pain and fever but no chills. She entered another hospital, where she was found to have bilateral pleural effusions. The pleural cavities were tapped twelve to fifteen times, and she developed empyema on the right, which was drained for several weeks. For the next three years, the joint pains were severer, but the patient was able to do her housework. For a year before entry, she had slight dyspnea on exertion and edema of the ankles, which disappeared at night. Two months before entry, she had a sudden onset of nausea, vomiting and diarrhea, with some pain around the umbilicus. The pain was somewhat relieved by vomiting but made worse by defecation. She had twelve to fifteen bowel movements a day, which were said to contain mucus and blood. The diarrhea ceased after treatment with Fuller's earth, and the patient improved considerably. A few days later, six weeks before entry, she developed severe dysphagia, at first with solid foods and finally with liquids; she was unable to swallow anything because of the severe pain and vomited about once a day.

She re-entered the outside hospital, where she was found to be obviously ill, pale and somewhat emaciated. Her left chest was dull to flat posteriorly below the angle of the scapula, and distant bronchial breathing and egophony could be heard in this area. The heart was moderately enlarged

to the left, the rate was 120 and grossly irregular, and the sounds were of fair quality. No murmurs were heard. The blood pressure was 110 systolic, 60 diastolic. The abdomen was normal. An x-ray film of the chest showed fluid at the left base; the heart was displaced to the left. The blood showed a red-cell count of 3,470,000 with a hemoglobin of 65 per cent, and a white-cell count of 4000 with a normal smear. The blood Hinton reaction was negative, as were Widal and undulant-fever agglutination tests. A gastrointestinal series was negative except for "slight delay with slight narrowing at the extreme lower end of the esophagus, consistent with a mild degree of cardio-spasm." A nasal tube was inserted. The patient was given fluid through the tube for forty-eight hours, after which she was able to take fluids and soft solids by mouth. The irregular heart beat proved to be paroxysmal, the attacks lasting a few hours. Her temperature and respirations were normal. After ten weeks, she was discharged on a bland diet. One month later, she entered this hospital for study.

Physical examination revealed a somewhat undernourished woman with signs of fluid or of a high diaphragm on the left, and a heart enlarged to the left, with sounds of good quality and no murmurs. The abdomen was normal. There was slight to moderate pain on motion of the neck, back, elbows, shoulders and knees. There was swelling and tenderness of a few of the small joints of the hands.

The temperature was 98.6°F., the pulse 90, and the respirations 20.

Examination of the urine was negative. The blood showed a red-cell count of 3,780,000 with 65 per cent hemoglobin, and a white-cell count of 4300 with 86 per cent polymorphonuclears. The nonprotein nitrogen of the blood serum was 19 mg. and the fasting uric acid 4.7 mg. per 100 cc.; the sedimentation rate was 1.94 mm. per minute. The blood Hinton reaction was negative.

X-ray study showed moderate decalcification of the lumbar spine and hands. There was slight narrowing of the vertebral joints, and some surrounding soft-tissue thickening. The chest showed enlargement of the heart to the left, with a rather prominent pulmonary conus. There was marked thickening of the pleura along the right axillary line from the apex to the diaphragm, and a small collection of fluid at the left base partially obscured the diaphragm and the apex of the heart. There were small areas of calcification at both lung roots. The nasal sinuses were clear. An electrocardiogram showed low T<sub>1</sub> and T<sub>2</sub>, inverted T<sub>3</sub>, shallow T<sub>4</sub> and normal Q<sub>1</sub>.

The patient was given a transfusion and discharged somewhat improved.

Two and a half months after discharge, she developed an ulcer on the left external malleolus, which did not heal. She also developed over the spine several flat nodules that were the size of a ten-cent piece and lasted for several weeks. Eight months after discharge, she suddenly had a severe shaking chill, with pain in the right chest, which was aggravated by inspiration. She became nauseated and vomited, and had a headache, but no stiff neck or increase in joint pains. She developed a temperature of 104°F., the blood pressure dropped, and the pulse became relatively slow. She re-entered the outside hospital, where physical examination revealed an obviously very ill woman with slightly cyanotic lips and fingernails. The heart was enlarged to the left, the sounds were loud, and there was a systolic murmur at the apex, with a suggestion of a gallop rhythm over the mitral area. The blood pressure was 85 systolic, 50 diastolic. Percussion of the chest was normal, but in the right mid-back there were crackling rales and definite bronchial breathing. The abdomen was slightly distended, and the liver edge was palpable 5 cm. below the rib margin and quite tender. There was a small ulcer on the external malleolus surrounded by an area of erythema.

The temperature was 105°F, the pulse 100, and the respirations 20.

The urine contained the slightest possible trace of albumin and 10 to 12 white blood cells per high-power field and occasional granular casts in the sediment. The blood showed a red-cell count of 4,100,000 and a white-cell count of 22,000, with 86 per cent polymorphonuclears. The sputum contained pneumococci, but the blood culture showed no growth.

Two days after entry, the area of rales and bronchial breathing had increased in size, and x-ray examination showed an area of consolidation at the right lung root. The blood pressure had risen to 126 systolic, 80 diastolic. The following day, the patient was symptomatically somewhat improved, but her temperature remained elevated and definite dullness could be detected between the angle of the scapula and the spine on the right. There was apparently a small amount of fluid in the abdomen, and there was slight edema over the sacrum and about the hips. Her urinary output became markedly decreased, and intravenous Salyrgan had no apparent effect. On the eighth hospital day, the urine contained a large trace of albumin, with occasional red cells and 10 to 15 white cells per high-power field, but no casts. The nonprotein nitrogen of the blood

serum was 70 mg. per 100 cc., and the chloride was 88 milliequiv. per liter. The patient was given 1000 cc. of concentrated glucose and sodium chloride, but her urinary output remained low. Twitching of the muscles developed, and the breath became urinous. The edema of the back and abdomen increased, and numerous nodules, 0.5 to 1.0 cm. in diameter, could be felt in both supraclavicular areas. The temperature remained high, and the pulse and respirations became more rapid. On the tenth hospital day, her condition became definitely worse. She developed generalized convulsions and died. The total urinary output in the last four days was about 300 cc.

#### DIFFERENTIAL DIAGNOSIS

DR. ALFRED KRANES: It is difficult to know how to begin on this problem because there seem to be so many apparently unrelated and independent episodes. I think the simplest way is to discuss each one independently and try to fit them together, if possible, into some sort of coherent picture.

The illness apparently began when the patient was twenty-six, and joint pains occurred about once a year. The description of the pain at the onset is not diagnostic of any type of joint disease with which I am familiar, although as the disease progresses, rheumatoid arthritis seems to be more of a possibility than any other type of joint disease; however, one does not expect patients with that disease to have a recurrence lasting only two weeks and disappearing, leaving her perfectly well for the rest of the year.

Rheumatic fever is another unlikely possibility. The only type of joint disease that will recur and subside, permitting a patient to be well in between attacks, is gout, but there is very little in this story to make one consider that diagnosis very seriously. So that I think we shall have to leave unsettled the diagnosis of her joint disease for the time being and go on to the next episode, which is the development of bilateral pleural effusion three years before admission. One would like to know what type of fluid was removed from this patient's chest. That we are not told, since it was done elsewhere. I presume it was a serous effusion. One would also like to know over how long a period she was ill with these effusions, since she had twelve to fifteen taps. I should interpret the empyema as probably being the result of repeated taps and not part of the underlying disease. The effusions must have lasted at least several months to have been tapped as many times as recorded here. What produced the pleurisy is far from clear. The usual causes of pleural effusion do not seem to fit this picture. Tuberculosis, of

course, is the first thing one considers, but it is quite unusual to get bilateral tuberculous effusions. They do occur but not very commonly. Furthermore, it is extremely unusual for a tuberculous effusion to require tapping so often as this. Apparently, the fluid reaccumulated rapidly. I think the chief argument against tuberculosis is that the empyema cleared up in several weeks. I certainly do not believe a tuberculous empyema would clear up so rapidly. Other causes for effusion, such as cancer, do not seem to fit this picture very well. It would be unusual to have a bilateral effusion with a malignant neoplasm. The patient might have had lymphoma, but I think it is extremely unlikely. There seem to have been no signs or symptoms of cardiac failure or renal or liver disease. I shall therefore leave the question of the pleurisy unexplained for the while.

The patient then developed a totally new chain of symptoms—nausea, vomiting and bloody diarrhea. No details are given, and I doubt whether any satisfactory explanation for it will be found, since it did not recur. The chances are that what ever produced it had subsided at the time of death, and very likely no anatomic explanation may be forthcoming for these symptoms. The patient also developed severe dysphagia, which may also have been related to the lesion causing the previous abdominal symptoms. We can speculate about the presence of some ulcerative lesion in the mucous membranes of the gastrointestinal tract, but there is no direct evidence. The symptom cleared up, and nothing further is said about it.

The patient again entered the hospital with a left pleural effusion, which apparently was asymptomatic. No fluid was present on the right, since the right pleural cavity was probably obliterated by the previous empyema. This time, her heart was found to be enlarged, and she was apparently having paroxysmal fibrillation, although the exact nature of the arrhythmia is not described. The x-ray report disturbs me a bit, because it states that the heart was displaced to the left. If that is so, one must assume that there was collapse of a considerable part of the left lung. There is no apparent reason for it, and I wonder if that is a correct observation. Whether the heart was displaced to the left, we shall have to leave open to question, I rather doubt it.

The physical examination when the patient entered this hospital is more or less confirmatory of what was previously found, except that there appeared to be less fluid than was described before. Whether that was removed in the meantime or absorbed spontaneously, we are not told. Again,

the heart was found to be enlarged, and the rest of the physical examination was normal except for pain and swelling of the joints. The urine examination was negative, which is important since the patient died of renal failure, this is the only report we have of a urine examination during the whole illness. The secondary anemia and leukopenia are again confirmed, but the rest of the laboratory data are of no value except for an elevated sedimentation rate.

The electrocardiogram does not mean much to me except that the patient may have had some myocardial damage. Following her discharge, she developed an ulcer over the left malleolus, which persisted until her death some six or eight months later. There seems to be no adequate explanation for it. Nothing is said about varicose veins, and she apparently was not syphilitic. The nodules over her spine interest me, and I should like to know whether they were subcutaneous or in the skin, and whether or not the skin was discolored. The description here does not help one very much. The nodules disappeared, apparently, in several weeks. Then the terminal event occurred, which was quite obviously a pneumonia. The rest of the story is that of a patient dying in uremia. What the cause of this terminal renal failure is, one cannot say from the record. The first question that comes to mind in a patient with pneumonia is whether chemotherapy was employed. Was she given any sulfapyridine or sulfathiazole?

DR CHARLES L. SHORT: No.

DR KRANES: That is too bad; because I had a ready explanation for the terminal renal failure. We shall therefore have to look for other explanations. Patients with overwhelming acute infections occasionally die in uremia, as some post-operative patients do. The blood pressure drops, and the renal blood flow diminishes and is followed by oliguria, anuria and consequent uremia. That is possibly the explanation here. In addition, there may be some underlying diffuse disease of the kidney, which shut down terminally. It does not seem, however, like an ordinary acute glomerulonephritis.

The whole problem seems to resolve itself into whether this patient had a number of different diseases explaining these separate episodes, or whether one can tie them together under one diagnosis. It would be more logical to explain everything on one diagnosis in this particular case, because it seems to me that there are no satisfactory multiple diagnoses that could be made explaining these separate episodes individually. One would like to find a disease that would explain them all. It would have to be quite a widespread dis-

ease involving the small blood vessels of the body or some diffuse vascular lesion of which these episodes were local manifestations. So far as I can see, there are only two diseases that would adequately explain this picture. One is periarteritis nodosa. The other is disseminated lupus erythematosus. So far as I know the pains of periarteritis are much more likely to be muscular or neuritic, rather than articular, nor does the disease cause recurrent pleural effusions—I have never heard of its doing so, at any rate. Furthermore the laboratory evidence is against it. Patients with periarteritis nodosa usually have a leukocytosis and very often an eosinophilia, neither one of which was present in this particular case.

The diagnosis of disseminated lupus—"acute disseminated lupus" is a very poor term because one cannot readily speak of an acute disease that has apparently lasted eleven years—seems to fit this picture better than anything else. It explains to me practically everything this patient had. Joint pains are very common in that disease. Recurrent pleural effusions or involvement of any of the serous surfaces is an outstanding characteristic. The gastrointestinal symptoms can be explained on that basis because patients with disseminated lupus develop lesions of the mucous membranes. To be sure, the lesions are more likely to be in the mouth or pharynx, but they can occur in the lower gastrointestinal tract as well. It could also explain the cardiac symptoms, because it frequently involves the heart, especially the pericardium. We have no evidence of pericarditis here, however. Occasionally it involves the endocardium, producing atypical vegetations on the heart valves, and cases have been described in which the myocardium has been involved, although the pathology of the disease is not at all clear. The diagnosis of disseminated lupus would also explain the ulcer of the leg, since it occasionally produces ulcerative lesions on the skin. Finally, many of these patients die of uremia. It is well known that people with disseminated lupus may have very extensive renal involvement. It is also interesting to note that patients with this disease, very often up until the time of death, show no evidence of renal disease, and then with the advent of some acute infection develop uremia. On the whole, disseminated lupus explains the picture better than anything else.

But there are objections to it. The first is its duration. Rarely do people with disseminated or visceral lupus live this long. The second and more important objection is the fact that throughout the disease no mention is made of skin lesions, unless possibly the nodules described represented

involvement of the skin. One hesitates to make a diagnosis of lupus without skin lesions, but in the disseminated type, the cutaneous manifestations of the disease are the least important part. Since everything else fits so well, I cannot allow the absence of skin lesions to deter me from making that diagnosis, which has one other great advantage, namely, that there are no characteristic pathologic lesions. I think among pathologists there is quite a controversy about whether or not there are any characteristic lesions. The consensus seems to be that there are not. That being so, Dr. Mallory may find very little aside from the acute terminal pneumonia. Consequently, although we may not be able to prove the diagnosis, Dr. Mallory will not be able to disprove it.

DR. SHORT: I saw the patient on both admissions to this hospital, and four or five days before she died. At the time she was in this hospital, there were two diagnoses that we considered: one was Dr. Kranes's diagnosis of disseminated lupus, and the other was a form of rheumatoid arthritis, with pleural effusion, pericarditis and myocarditis. We had the same objections to lupus that Dr. Kranes had—the lack of any characteristic skin lesions. It is fair to say that she did have some small scattered papulopustular lesions, but we were never quite sure whether they meant anything or were just what one might see on anybody. The patient also had what seemed to be a mild acne rosacea; at least we thought it was, and did not consider it characteristic of lupus. The other objection was the duration of the disease—she had been ill for ten years, although she was in relatively good shape. When I saw her just before she died, I could add nothing more to a consideration of the primary diagnosis. I thought she had an intercurrent pneumonia and cardiac failure.

At the time I saw her here, there was no evidence of renal failure. I think it is fair to say that Dr. Walter Bauer and I both saw this patient, and that I leaned toward atypical rheumatoid arthritis and he toward acute disseminated lupus.

#### CLINICAL DIAGNOSES

Acute disseminated lupus erythematosus?  
Rheumatoid arthritis?  
Pneumonia.  
Terminal uremia.

#### DR. KRANES'S DIAGNOSES

Disseminated lupus erythematosus.  
Terminal pneumonia.  
Uremia.

## ANATOMICAL DIAGNOSES

Acute disseminated lupus erythematosus  
 Bronchopneumonia, bilateral  
 Miliary abscesses of right upper lobe of lungs  
 Pericarditis, chronic, fibrous, obliterative  
 Mediastinitis, chronic, fibrous.  
 Pleuritis, chronic, obliterative  
 Splenomegaly  
 Lymph node enlargement, general  
 Pulmonary congestion.  
 Arteriosclerosis, aortic, minimal  
 Peritonitis, chronic, fibrous, localized  
 Perisplenitis  
 Ascites

## PATHOLOGICAL DISCUSSION

DR TRACY B. MALLORY: The post mortem examination, as Dr. Krane predicted, still leaves several loopholes for doubt. The positive findings can be listed rather quickly. There was a complete fibrous obliterative pleuritis on both sides, with no fluid. The pericardium was quite markedly thickened, and Dr. Eugene Sullivan, who made the post-mortem examination, also thought that the surrounding mediastinal structures showed more fibrosis than usual. The pericardium was totally adherent to the heart, and the two together weighed about 500 gm. The right ventricle seemed to be slightly dilated and was definitely a little hypertrophied. There was no endocarditis, and no myocarditis was made out. The liver was enlarged, and showed rather marked central congestion, which merely seemed to be evidence of heart failure. The spleen was greatly enlarged, weighing 700 gm. It should have been readily palpable. The kidneys were also large, weighing a little over 400 gm. Through out the body, all the lymph nodes were quite notably enlarged, ranging from 0.5 to 1.5 cm in diameter. The retroperitoneal, bronchial, axillary and inguinal glands showed definite lymphadenopathy. The joints showed marked synovitis but no evidence of rheumatoid arthritis.

On microscopic examination, there is very little to add. There was a fibrous pericarditis, pleuritis, terminal pneumonia, some slight central necrosis of the liver and nothing significant about the spleen. The kidneys showed discouragingly little. An occasional glomerulus showed focal glomerulitis of a tuft, or of a portion of the tuft. They certainly did not look like the kidneys of renal failure and uremia. The convoluted tubules were a little swollen. Nowhere in the body were we able to pick up any vascular lesions that would suggest periarthritis.

We have the records of autopsies on 24 cases of disseminated lupus, and on reviewing them it is apparent that nothing is constant. Pneumonia is the commonest finding, but that is always just a terminal event and nonspecific in character. Pleuritis and pericarditis occur in the great majority of the cases. Ascites is less common, and endocarditis is uncommon. A diffuse lymphadenopathy is almost regular. Splenomegaly is quite typical. Nephritis, when one hunts very hard for minimal changes, can be found in 70 per cent of the cases. At the time of autopsy, the skin lesions could be made out in 14 cases. The existence of a real adhesive pericarditis, particularly a mediastinopericarditis, is unusual in these cases, but we have seen it and I should be strongly inclined to side with Dr. Krane and regard this case as one of disseminated lupus despite the absence of characteristic skin lesions at any time during the disease.

DR. KRANE: You have to make that diagnosis mostly on clinical grounds.

DR. MALLORY: Yes. We can add two more points that are consistent from the anatomic point of view: the slight changes in the kidney are of a type we see most frequently in lupus, and the changes in the lymph nodes are of the type we regularly see in lupus. Furthermore, the autopsy ruled out rheumatoid arthritis, tuberculosis and periarthritis nodosa, the only other likely possibilities in this patient.

## CASE 27302

## PRESENTATION OF CASE

*First Admission.* A forty seven year-old laborer entered the hospital complaining of hemoptysis.

At the age of twenty three years, the patient had had a penile chancre, and as a known syphilitic, he presented himself at the Out Patient Department seventeen months before admission for advice regarding the performance of manual labor. Fluoroscopy revealed a slight but definite enlargement of the heart in the region of the left ventricle, with a concave left upper border. The ascending aorta was prominent to the right, with increased pulsation; the hilar shadows and aortic knob were normal. On physical examination, the heart was regular at 80, with a moderately loud early diastolic murmur along the left sternal border. There was no Corrigan pulse, and the blood pressure was 205 systolic, 105 diastolic. Examination of the nervous system, as well as that of the pupils, fundi and fields, was negative. A blood Hinton reaction was positive, a lumbar puncture

normal, and the spinal-fluid Wassermann test negative. Antisyphilitic treatment was instituted, and the patient was allowed to do light work; he remained well without signs of heart failure, the blood pressure running between 205 and 140 systolic, 105 and 90 diastolic.

Six weeks before admission, the patient caught a cold in his chest, with a dry cough that finally produced small amounts of thick yellow sputum. On the day of admission, he suddenly began to cough up small amounts of bright-red blood every two or three minutes, so that at the time of observation he had raised about one and a half cupfuls. There were no accompanying symptoms and no pain.

In the hospital, there were no more hemoptyses, and on examination the patient appeared perfectly well. The fundi showed tortuous silverwire vessels, with dilatation of the veins at the points of crossing. There was a moderate pulsation of the neck vessels; the blood pressure was 180 systolic, 95 diastolic. Some confusion seemed to exist concerning the character and type of the heart murmurs. Systolic and diastolic murmurs were heard both at the apex and at the base by the various examiners in the Out Patient Department and in the hospital; however, the consensus leaned heavily toward the presence of a moderate systolic blow on the aortic area, with a moderate aortic diastolic murmur along the left sternal border. Scattered wheezes were heard throughout both lungs.

The temperature, pulse and respirations were normal.

The blood showed a red-cell count of 5,130,000 with a hemoglobin of 96 per cent, and a white-cell count of 9500. The blood Hinton reaction was positive. Examinations for tubercle bacilli in the sputum were negative.

An x-ray film of the chest showed no change, but on the fifth hospital day a line of increased density perpendicular to the diaphragm was present in the medial portion of the right lower-lung field, with a wedge-shaped area of consolidation close to it, apparently far posteriorly. No fluid was seen in the pleural cavity.

The patient's stay in the hospital was uneventful, and two weeks after admission x-ray study of the chest showed that the area of dullness had completely disappeared, so that he was discharged.

*Final Admission* (two years later). Although there was perhaps some slight decrease in exercise tolerance, the patient had felt well doing light work. Antisyphilitic treatment had been kept up in the Out Patient Department, but the blood Hinton reaction remained positive; the blood pressure ranged around 190 systolic, 100 diastolic.

Eight months before admission, an x-ray film of the chest showed that the heart had increased slightly in size since the previous examination, the enlargement being in the left ventricle. The aorta had become slightly wider and showed a Corrigan type of pulsation.

In recent months, a to-and-fro murmur over the aortic area and down the left border of the sternum was noted frequently in the Out Patient Department, as well as an apical diastolic blow.

Three hours before admission, after a meal, the patient was seized with a sudden, severe, non-radiating substernal pain, which was constant and still present on admission. Nausea and vomiting soon followed, with rapid cyanosis and cold, clammy extremities.

On examination, the patient was well developed and well nourished, orthopneic, cyanotic, cold, clammy and sweating. The eyeballs were roaming, the pupils equal. The heart was enlarged, the apex being in the anterior axillary line. The sounds were of fair quality, with occasional extrasystoles and a diastolic murmur along the left sternal border. The pulse was barely obtainable, the rate 90, and the blood pressure 60 systolic, 0 diastolic. The lungs were clear, and the respiratory rate was 25. The abdomen was normal, and there was no peripheral edema.

An electrocardiogram showed a normal rhythm, with a rate of 90 and a PR interval of 0.15 second. There was a depressed take-off in ST<sub>1</sub> and ST<sub>2</sub>, with prominent T<sub>1</sub> and T<sub>2</sub>. T<sub>3</sub> was upright, and R<sub>4</sub> low, with a depressed take-off in ST<sub>4</sub>.

The patient died eight hours after admission, without change in his physical signs.

#### DIFFERENTIAL DIAGNOSIS

DR. EDWARD F. BLAND: As a background for this patient's acute and rapidly fatal illness, I think there can be no reasonable doubt that he had a variable but considerable degree of hypertension and enlargement of the heart, which I am inclined to attribute mostly to the hypertension, rather than to the aortic regurgitation that was also present. The degree of aortic regurgitation seems not to have been great, certainly as judged by the blood-pressure (pulse-pressure) readings taken from time to time. Secondly, there apparently was no doubt in the minds of those who had this patient under their care that he also had cardiovascular syphilis, and I agree with that impression because he had a history of a penile lesion some twenty years before admission, a positive blood Hinton reaction, an aortic diastolic murmur, and fluoroscopically a slightly dilated ascending aorta, with increased pulsations. Although there was some confusion about the murmurs, I

think we had better rely on the interpretation of the majority, and accept the aortic diastolic murmur as diagnostic of organic aortic regurgitation, perhaps of only slight to moderate degree. The syphilis was vigorously treated.

I wonder if we might look at the X ray films and ask the X ray Department if they agree that syphilitic aortitis was present.

DR JAMES R. LINGLEY: This is the first film taken, showing enlargement of the left border, which was due to left ventricular enlargement. The aorta is tortuous, and there is some bulging of the anterior portion of the ascending aorta, but the dilatation is very slight. I think that from the X ray appearance it could be simply due to hypertension, and does not necessarily indicate syphilitic aortitis. This was the area of density described in the mid portion of the right lower lobe—rather a hazy indefinite area extending in a wedge posteriorly into the chest wall.

DR BLAND: Was that film taken two years before the final illness?

DR LINGLEY: Yes.

DR BLAND: Dr Aubrey O. Hampton and others make the point that calcium in the ascending portion and not visible elsewhere in the aorta is strongly suggestive of syphilitic scarring. Do you see any evidence of that?

DR LINGLEY: No. I see no evidence of calcium in the first portion of the aorta. These are later films, showing possibly a little more prominence in the region of the left ventricle, the aorta may be slightly larger, but I think it is rather doubtful.

DR BLAND: There is certainly no sacular aneurysm.

DR LINGLEY: No.

DR BLAND: There is no calcified aortic valve that you can see?

DR LINGLEY: No.

DR BLAND: Although the X ray films are not so helpful as I had anticipated, I think this patient probably had cardiovascular syphilis, with syphilitic aortitis; this was well treated, and the course suggests that this condition was not actually progressive. He got along very well, and there was not much evidence, either from symptoms, from signs or from interval X ray study, of a progression in the cardiovascular syphilis. On the first admission to the hospital, two years before he died, he had had a respiratory infection prior to entry. He was raising some blood, and developed what looks to me from the X ray description more like an infarct of the lung than pneumonia. I think this episode probably had no bearing on the later terminal acute illness.

Now we come to the last illness, the patient having had no angina, no paroxysmal dyspnea and no other cardiac symptoms in the interim. Patients with cardiovascular syphilis are notoriously apt to die suddenly either with or without preceding cardiovascular symptoms. It is difficult at first glance not to connect the two in this patient. Some die suddenly from rupture of a large sacular syphilitic aneurysm, which this patient did not have. Others die of acute coronary insufficiency, usually associated with free aortic regurgitation, indicating that the process has extended to a considerable degree about and beyond the mouths of the coronary arteries. Most of these patients, however, have some indication of acute coronary insufficiency before the sudden exitus. I do not believe this patient had free aortic regurgitation, and hence he probably did not have extensive narrowing of the coronary ostia. We can conceive that the coronary arteries were abnormally high in the aorta at their origin and perhaps being extensively involved without much indication of involvement of the aortic valve as such. I think that, however, is unnecessarily fanciful and needs no further consideration here.

How else, then, could cardiovascular syphilis suddenly cause this patient's death? It is well known that patients with syphilis may die abruptly and unexpectedly after specific intravenous treatment. This patient had been under treatment for some time without suspicious reactions, and nothing is said of very recent antisyphilitic therapy, so that I think we must assume his death was not related to therapy. In view of the foregoing remarks and with some hesitation, I shall say that I think cardiovascular syphilis had no direct bearing on his death.

What else might he have had? One must consider, at least in passing, a massive pulmonary embolus. When anyone dies in this fashion with severe pain in the chest, one has to keep that in mind. Furthermore, this man had probably had a small pulmonary infarct two years before, but I do not see that we have any reasonable evidence to attribute his death to a large pulmonary embolus. He had not been in bed. There was no infection, no obvious circulatory stasis, no swelling of the legs to indicate local vascular disease, and his veins were not engorged prior to exitus. Therefore, I am willing to discard pulmonary embolism from further consideration.

We are left with the two conditions, one of which seems to me most likely to have caused his death. First, and on the line of chances most likely, is a coronary thrombosis (myocardial infarct). The patient may certainly have had an

acute coronary thrombosis. One can work up a good case either for or against that diagnosis. Somewhat against it was the absence of preceding angina pectoris. Of course, that is not necessary. Secondly, it is a little unusual to have such severe pain as this man had beginning so abruptly; in fact, as described it was maximal at the onset. The discomfort with coronary thrombosis usually begins, as the patient often describes it, as "indigestion," which progressively increases in severity. In a few minutes to an hour or two, it becomes severe, but it is usually not maximal right from the beginning. Perhaps the description here is faulty, and I am too much disturbed by the abrupt onset. Perhaps it did start, after all, with less severe intensity and build up. However, I find other points that influence me somewhat away from this diagnosis. Ordinarily, with coronary thrombosis and myocardial infarction sufficiently extensive to end fatally in a few hours and with pain of this severity, it generally spreads somewhere else, usually to the arms, to the throat or to the back. I am bothered a little by the fact that this severe pain, if of coronary origin, remained so localized. Another point, — I am arguing against coronary thrombosis, and I think arguing myself into a hole, — the electrocardiogram is rather non-committal. It was probably taken in the Emergency Ward, because the record is obviously from a portable machine. As stated in the record, it is surprisingly close to normal and certainly not what one would expect if one were dealing with coronary thrombosis. There is a very slight depression of ST<sub>1</sub> and ST<sub>2</sub>, and no elevation of the ST interval in any lead. These are, at most, minor changes, and besides we do not know that this patient may not have been on digitalis prior to entry. Certainly, one cannot support a diagnosis with this electrocardiogram. The pulse rate was quite slow, in the absence of block, for a patient with a large myocardial infarct: it was only 90, and the degree of peripheral collapse was extreme. The drop in blood pressure, however, fits in beautifully with coronary thrombosis.

The next possibility, of course, is dissecting aneurysm. The abruptness and severity of the pain at the beginning is influencing me considerably in the latter direction. Usually, with dissecting aneurysm, the pain does not radiate to the arms, unless one of the vessels to the extremity becomes obstructed at its mouth. It often does go to the back and down into the abdomen, and even to the legs. In this patient, the pain *did not* radiate at all, and the blood pressure dropped rather alarmingly. Both are somewhat against dissecting aneurysm, but do not rule it out. The low pressure might be due to local disturbance of the vessels.

But that is forcing the point a little. The patient continued in a critical condition and died about eleven hours after the onset. The strongest argument against dissecting aneurysm is that we believe this patient had syphilitic aortitis, and the combination is certainly most unusual. I cannot think of any other argument either for or against these two most likely possibilities, and I prefer the latter.

In closing, I suggest as the diagnoses: hypertension and hypertensive heart disease, cardiovascular syphilis (not extensive), aortic regurgitation (slight) and dissecting aneurysm of the aorta. I prefer the latter to coronary thrombosis.

DR. WILLIAM B. BREED: Would Dr. Lingley have talked very much about the aorta or aortitis if he did not know that the patient had a positive blood Hinton reaction and had been treated for syphilis?

DR. LINGLEY: No. The only thing from the x-ray point of view that suggests aortitis is the fluoroscopic note of increased pulsations. From the films alone, I could not make a diagnosis of syphilitic aortitis.

DR. BREED: Do you think the pulse rate of 90 is a fairly good argument against occlusion?

DR. BLAND: No; it is no argument either way. Do you not think that most people who have myocardial infarction of this degree, and who fail and die in the course of twelve hours, show some signs of heart failure either by a gallop rhythm or by rales at the lung bases?

DR. BREED: I do not know that that is a good enough argument.

DR. WYMAN RICHARDSON: I should like to ask whether most patients with dissecting aneurysm do not have an even higher blood pressure than this. It has been my experience that most of them have systolic pressures over 200.

DR. BLAND: Most of them do, but not all. Some are under 200. This patient's age does not help us either way. Of course, one can get dissection on bases other than media necrosis cystica. Dr. George M. Bartol, of the Boston City Hospital, recently demonstrated at a meeting of the New England Heart Association the case of a seventy-five-year-old man with calcific disease of the aortic valve and superimposed subacute bacterial endocarditis. This man developed between two cusps of the aortic valve a mycotic aneurysm that broke through into the middle coat of the aorta and dissected widely. There was no evidence in this case of cystic degeneration of the media.

DR. BENJAMIN CASTLEMAN: But there was an infectious process.

DR. BLAND: Yes; but does it not illustrate that,

very rarely, degeneration of the media is not necessary to make possible a widespread dissection?

DR. CASTLEMAN. Years ago, it was believed that arteriosclerosis per se was the etiologic agent. The intima was arteriosclerotic, and the tear in the media occurred at the site of the arteriosclerotic plaque. We have had seven or eight such cases, but in those the dissection was limited to a short segment, not more than a centimeter or two, and did not produce any symptoms—just incidental autopsy findings.

DR. BLAND: Do you like the abruptness and severity of the onset in this case, Dr. Breed, in relation to your diagnosis of coronary disease?

DR. BREED: That does not bother me.

#### CLINICAL DIAGNOSES

Coronary thrombosis.

Syphilitic and hypertensive heart disease

Syphilitic aortitis and aortic regurgitation

#### DR. BLAND'S DIAGNOSES

Hypertension and hypertensive heart disease.

Cardiovascular syphilis

Aortic regurgitation, slight.

Dissecting aneurysm of the aorta.

#### ANATOMICAL DIAGNOSES

Dissecting aneurysm of aorta, with rupture into pericardium.

Media necrosis aortica cystica.

Syphilitic aortitis.

Cardiac hypertrophy.

Endocarditis, chronic, rheumatic, with stenosis, aortic.

#### PATHOLOGICAL DISCUSSION

DR. CASTLEMAN. The autopsy showed an enlarged heart, weighing 700 gm., and slight coronary disease without occlusion. The aortic valve showed definite interadherence of the cusps at their commissures, a finding quite characteristic of old rheumatic infection. There was no evidence of separa-

tion of the cusps to suggest syphilis. On the other hand, the aorta above the valve in the ascending portion and in the arch showed stellate scarring and linear tree barking characteristic of syphilis. This was confirmed microscopically. The ascending aorta was dilated, and measured 11.5 cm. in circumference. About 2 cm. above the aortic valve was a transverse tear in the intima. The tear was the largest we have ever seen, measuring 8 cm. across. Extending backward from the tear was characteristic dissection of the media of the aorta as far as the annulus, producing constriction of both coronary arteries, a circumstance that may cause anginal pain. As a matter of fact, the dissection must have continued into the coronary arteries because grossly there were subendocardial myocardial hemorrhages, and on microscopic examination there was adventitial hemorrhage around a few of the smaller myocardial vessels. Perhaps this was merely adventitial expansion of the blood around the coronary arteries. The dissection had not ascended above the point of intimal tear, stopping short at the point where the syphilitic aortitis became evident. The external tear had occurred into the pericardial cavity, and the patient presumably died of cardiac tamponade. As in another case we have recently discussed, there was hemorrhagic extension through the adventitia of the aorta to the adventitia of the main pulmonary artery and then into the lung. In summary, therefore, this man had rheumatic heart disease with aortic stenosis and probably some degree of regurgitation, syphilitic aortitis and a dissecting aneurysm of the aorta, with rupture. Sections of the aorta showed in addition to the syphilis a diffuse mucoid degeneration of the media, and in a few areas there were suggestive cyst formations. The cause of the dissecting aneurysm was most certainly the medial necrosis, and the syphilis was probably only an incidental finding. It is quite possible that the syphilitic scarring prevented the distal extension of the dissection.

DR. BLAND: Was the mitral valve all right?

DR. CASTLEMAN: Yes.

## ANNUAL MEETING OF THE AMERICAN MEDICAL ASSOCIATION

THE annual meeting of the American Medical Association taxed the capacity of the hotels at Cleveland and even filled to overflowing a large lake steamer moored at the docks. It should be noted that the House of Delegates finds it an increasingly difficult problem to select cities capable of handling this tremendous gathering of physicians—hotel accommodations must be adequate, and at the same time, sufficient meeting places must be available for the House of Delegates, the various sections and the scientific and commercial exhibits. In spite of the crowding, the meeting was an outstanding success. The scientific exhibits were remarkable in their completeness and ar-

range, and the papers were up to their usual standard of excellence. The Cleveland Public Auditorium proved adequate for the meetings of the sections and for the exhibits.

The general atmosphere of the House of Delegates was saturated with preparedness, approached from military, social and economic angles. President Nathan B. Van Etten, in his address to the House, again urged a department of health at Washington, headed by an officer of Cabinet rank, a suggestion that, up to the moment, has received but little sympathy in Washington. President-elect Frank H. Lahey stressed the necessity of subordinating all trivialities and conflicts of opinion to the pressing need of national unity and preparedness.

The Committee on Preparedness, appointed at the meeting in New York City last year, presented through its chairman, Dr. Irvin Abell, a lengthy report detailing its activities. This report is presented in full in the June 21 issue of the *Journal of the American Medical Association* and should be read carefully by all physicians. It stressed particularly the deferment of medical students and interns by local draft boards, so that a constant supply of well-qualified physicians should continue. On recommendation of this committee, the House later adopted a statement to be sent to the Secretary of War and the Surgeon General of the Army urging the War Department to provide some form of military status for all students in approved medical schools and for all premedical students accepted for enrollment in approved medical schools, to make clear that in preparing themselves to become physicians such men are not trying to evade their responsibilities or the draft.

The Committee also recommended, and the House adopted, a resolution urging the creation by the Government of a central authority for the procurement of physicians for assignment to the United States Army, Navy and Public Health Service and to the civilian and industrial needs of the country. This agency would contain in its membership representatives from the civilian medical profession, and would have authority to determine who should be called to service and

who should stay at home. Although the Committee on Preparedness has the machinery to prepare lists of available physicians and is able to evaluate their capabilities and, in some measure, their necessity at home, it has no power to enforce its judgment; neither has the Government at the present time. This authority would have some power, and should function so that whole communities would not be left without adequate medical care.

A certain amount of unrest among many physicians in regard to the various specialty boards was brought into the open by two resolutions presented to the House. The first proposed a committee from the House of Delegates to confer with the various boards, and the second that efforts be directed toward creating a board of general practitioners. Neither resolution prevailed. It was the consensus of the delegates that the boards were independent of the American Medical Association, being more or less controlled by the Advisory Board for Medical Specialties.

The House of Delegates, in executive session, listened to a résumé of the trial of the American Medical Association and certain of its constituent societies in Washington and voted, without a dissenting vote, to authorize the Trustees to appeal the verdict to the Court of Appeals of the District of Columbia and, if necessary, to the Supreme Court of the United States, so that it shall once and for all be determined whether medicine is a trade or a profession.

A significant feature was the designating of the 1942 meeting at Atlantic City as the Pan American Session, to which the South American medical societies will be asked to send special representatives.

The free and open discussion, the careful thought given by the reference committees to each resolution and the high percentage of attendance at the meeting speak well for the quality of men selected by the constituent state societies as delegates to the House of Delegates. This is as it should be, since the House of Delegates is the only body that has the power to determine the policies of the American Medical Association.

## THE EPIDEMIOLOGY OF CANCER

ALTHOUGH, in its narrower interpretation, the term epidemiology can hardly be applied to a non-infectious disease such as cancer, nonetheless the methods applicable to the study and control of epidemic diseases are so serviceable in advancing the knowledge of cancer and its control that the utilization of the term in this broader sense is perhaps justifiable. The epidemiologist deals with disease processes in mass and is concerned not so much with the problems of the care of the patient as with learning all he can regarding the etiology, predisposing factors, nature and prevalence of the sickness. With these in mind, means of prevention and means of control may, at least to a limited degree, be worked out.

The first problem to be settled with regard to cancer is that of its incidence. Work has been done in this field for many years, and modern mortality statistics are fairly accurate. But even yet there is very little useful information regarding the morbidity of cancer. As more and more cases are cured, and as the different types of the disease have means of therapy developed for them, it becomes of increasing importance to know as many as possible of the details of incidence. In several localities, morbidity studies are now being carried out, and it is hoped that much may be learned from them.

The increasing accuracy of mortality statistics and the mass of data accumulated in hospitals have already demonstrated many things about cancer. Although it was once considered a disease of old age, it is recognized that certain types occur early in life, and some, such as tumors originating from nerve cells, are almost entirely restricted to that period. In general, it is true that the prevalence of cancer rapidly increases with the advance in years. Sometimes a given type of cancer, such as osteogenic sarcoma arising in bone, may have two different peaks of incidence in relation to age—one in adolescence and the other in old age. The occurrence of this tumor in old age is clearly correlated with a predisposing condition—Paget's disease in the bone. From these few examples, it may be seen that cancer is not one disease, but

rather many diseases different in their courses, in their modes of treatment and, presumably, in their causation.

Some years ago it was noted that workers in certain of the aniline-dye industries developed cancer of the bladder with unusual frequency. By careful observation of these cases, and comparison of the incidence of bladder cancer with that of the general population and with that of workers in other portions of the industry, it was finally found that one particular substance—naphthylamine—was the responsible factor, and that by preventing exposure to it this particular hazard could be overcome.

Still another example of special causation of a particular type of cancer is afforded by a group of miners at Schneeberg, in Austria, who worked in a mine where the ore was radioactive; because of the inhalation of radioactive particles over a period of years, many of these men developed cancer of the lung. Furthermore, the early workers in x-ray and radium provided excellent, though unfortunate, examples of the potential danger of these useful diagnostic and therapeutic tools, since the toll of skin cancer among this group of workers was exceptionally high.

In the past year or two, it has begun to be realized that an industrial hazard only recently thought to be fairly clearly understood might also produce neoplastic disease. The production of severe anemia by benzol poisoning has been known and recognized for some time, but the fact that with slight exposures a hyperplastic response of the marrow, leading to the development of leukemia, might occur has only recently been appreciated.

Race is a significant factor, but one difficult to evaluate, since many aspects of environment, habit and diet may be associated with it. The rarity of cancer of the cervix in Jewish women and the frequency of carcinoma of the stomach among Scandinavian races are examples of this type of race selectivity. Still another complicating factor in an understanding of the incidence of malignant disease is the existence of individual susceptibility. It has been clearly demonstrated that the occurrence and cure of one cancer con-

fer no immunity, but rather that there is a definite susceptibility of a person who has one cancer to the development of a second, or even of a third. These matters of racial and individual susceptibility are most troublesome when it comes to evaluating statistical material.

Certain lesions, some inherited and some acquired, are clearly recognized as precancerous. Thus, the occurrence of benign polypoid growths of the large intestine is an inherited abnormality, and such growths are a very frequent source of cancer of the large intestine. In the same way, certain acquired abnormalities subsequently lead to the development of cancer. Thus, there is a greater proportion of skin cancer in the total of all cancer in the South and Southwest than there is in New England, apparently directly ascribable to a greater exposure to sunlight, heat and dust. The woman who develops cystic disease of the breast develops a precancerous lesion. This type of disease process, quite prevalent, has been regarded by some as harmless, by others as a definite precursor to cancer. Only recently has a clear-cut answer to this problem been reached. On the basis of a large number of women followed for an average of over nine years, it was found that those women who developed chronic mastitis before the menopause had eleven and a half times as much cancer of the breast as the normal population did; after the menopause the difference was less striking—two and a half times as much. Furthermore, it is practically axiomatic that a cancer never develops in a normal mouth. Instead, one finds as predisposing factors such changes as leukoplakia, syphilis of the tongue and chronic irritation from bad teeth.

Progress will continue, if, as one learns more regarding the varied aspects of cancer, the disease is studied by epidemiologic methods, rather than by considering each case as an isolated problem. Means of prevention of certain types of cancer are already available. Methods of therapy are steadily improving, and their early application will lead, even without further advances in knowledge, to a marked lowering of the cancer death rate.

## MEDICAL EPONYM

## JACKSONIAN EPILEPSY

This condition bears the name of John Hughlings Jackson (1834-1911). The following quotation was written by an anonymous contributor to the column, "Reports of Medical and Surgical Practice in the Hospitals of Great Britain," and appeared in the *British Medical Journal* (1: 773, 1875) under the title, "London Hospital: Clinical memoranda of a series of interesting cases of nerve disorder now in hospital (under the care of Dr Hughlings Jackson). . . ."

... In the convulsions spoken of (commonly called epileptiform convulsions), a good deal occurs before the patient loses consciousness. One patient gave a very vivid account of what Dr Hughlings Jackson calls the "march of the spasm." This patient's fit begins in his left index finger and thumb, it then passes up the arm, and affects the face, and next passes down the leg. It is the rule that fits which begin in the hand should begin in the index finger and thumb when they begin in the foot, they usually begin in the great toe.

Speaking of these cases, and with reference to their difference from such cases as are commonly called epilepsy par excellence, Dr Hughlings Jackson said that he thought the abrupt division into cases with and cases without loss of consciousness was not even justifiable on grounds of convenience. The distinction was, he insisted, into cases where consciousness was lost first of all, very early or late in the paroxysm.

## MASSACHUSETTS MEDICAL SOCIETY

SECTION OF OBSTETRICS  
AND GYNECOLOGY\*DEATH ASSOCIATED WITH PERITONITIS  
FOLLOWING CESAREAN SECTION

A thirty seven year-old para VII had consulted no physician until labor started. Shortly after the onset of labor, the patient began to bleed from the vagina and was sent into the hospital. The membranes ruptured shortly after arrival in the hospital, at 6 35 p.m., and labor ceased. The hospital notes state that there was a good deal of bleeding during the night, and that at 3 30 the following morning a consultation was held. No diagnosis was made, and a cesarean section was performed. The pulse at that time ranged from 140 to 150. When the abdomen was opened, the baby and the placenta were found free in the abdominal

cavity. The uterus had apparently contracted, and there was no evidence in the note that the uterus had ruptured. The diagnosis of the operator was abdominal pregnancy, and the abdomen was closed. The patient was not transfused. She died three days after operation, apparently of peritonitis.

*Comment.* The record on this case is very incomplete. The past history mentioned only that she had had no evidence of cardiac or renal disease. The blood pressure was not recorded, and the only reference to the pulse was that before operation it had risen to 150. Although the death certificate attributes this death to abdominal pregnancy, such a diagnosis is extremely unlikely. Abdominal pregnancies are not characterized by excessive vaginal hemorrhage. The large amount of external bleeding in this case suggests that the placenta had been attached to the uterus, and the fact that the baby and placenta were reported to have been found free in the abdominal cavity, the placenta being without any attachment, bears out this diagnosis.

The observation that shortly after 6 35 p.m. labor ceased but hemorrhage continued is interesting. It is perfectly possible that, when labor ceased, rupture of the uterus occurred. Uteri do spontaneously rupture at term. An operation, followed by transfusion, when this patient arrived, after an intelligent diagnosis had been made, would probably have saved her life. To avoid such disasters, patients must be followed during pregnancy. Those financially unable to have private physicians must be taken care of by some sort of clinic. Without prenatal care, there can be no personal relation between patient and obstetrician, which is a vital part of successful obstetrics. It is difficult to understand how this patient, who was reported to have been bleeding very freely by vagina at 6 35 p.m. and who continued to bleed for nine hours, passing clots, had no vaginal examinations during this time for the purpose of establishing an intelligent diagnosis. Had an abdominal pregnancy existed, which is unlikely, and had it been diagnosed at 6 35 p.m., an operation at this time would probably have saved the patient's life.

This death can be attributed to either ignorance or indifference on the part of the medical attendant. A higher sense of responsibility throughout the profession at large can be acquired only by improved education in medical schools, by additional training in a hospital after graduation and by a greater sense of responsibility on the part of the hospital authorities so that they will demand of those physicians practicing in their institutions

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section. Letters should be addressed to Dr. Raymond S. Titus, Secretary, 339 Dartmouth Street, Boston.

a higher standard of obstetric routine. In this column, it has frequently been emphasized that hospital trustees are ultimately responsible for both good and bad medicine, and good and bad obstetrics, as practiced in their institutions. They have the power to regulate obstetrics in their hospitals, and until supervised obstetrics is practiced in all institutions, such fatalities as this will be repeated.

### INFANTILE PARALYSIS\*

Almost every summer, when infantile paralysis breaks out in some section of the country, there is an extraordinary degree of apprehension. This is not so much because of the large number of cases, as compared with epidemics of other diseases, but because of the fear of paralysis. Then, too, the unexpectedness with which the disease strikes and the uncertainty as to where it will appear add to the alarm. This feeling of helplessness is responsible for a pressing demand for more knowledge about the disease. As a result, infantile paralysis has been studied much more closely than many of the far commoner diseases to which we seem to have become more accustomed.

In many diseases, the cause is quite apparent from some striking circumstance; for example, the connection with the sick parrot in psittacosis and with the dog-bite in rabies and the exposure to a case in smallpox or measles or to the carrier in typhoid fever. But in infantile paralysis, no one circumstance immediately tells us which way to turn in attacking the problem. Any theory becomes a subject of study. Through the years, a great variety of seemingly contradictory findings have accumulated. Moreover, the clinical disease is sparsely distributed, and the available tools to study it in the laboratory are so restricted that studies in the field or experiments in the laboratory have often been limited to such small numbers that it has been difficult quickly to recognize the important or to rule out the unsound theories. Since it is difficult to discriminate between significant and insignificant observations, it is not easy to harmonize the various findings into a convincing concept. The result has been that we find all sorts of conflicting hypotheses, often based on small bits of evidence, and with seeming preference for those that have a more hopeful sound or match in oddness the vagaries of the paralytic disease. If, instead of forming a new theory every time a new bit of evidence is collected, the many pieces of evidence are fitted together like the jigsaw puzzle, we can begin to see a picture that could hardly be imagined from even the closest examination of the pieces separately. From the maze of collected studies, a few facts stand out clearly, facts that could not be discovered from the study of individual cases or epidemics, or from any single experiment.

The dissemination of the virus far exceeds the occurrence of the frank disease. Evidence that the virus is generally and rather uniformly widespread is seen in the geographic prevalence of the disease—we find it all over the globe; in the difference in the ages at which it occurs in city and country populations; and the finding

that many persons become immunized who have never had any symptoms of the disease. In striking contrast, the occurrence of the paralytic disease is restricted to a small fraction of those exposed to the virus.

Many who come in contact with the virus show no symptoms. More of the milder forms of the disease are now being recognized, so that a diagnosis of infantile paralysis no longer means, as it did a few years ago, inevitable paralysis. And we are beginning to ask ourselves when we see these primary symptoms: Will this be infantile paralysis, or is it merely a harmless infection with its virus, trivial in itself, but taking its full part in passing the virus along and keeping it in circulation?

Now that we understand that this virus, which is so widespread,—perhaps as widespread as measles,—is harmless to the vast majority of people, we might do well not to concentrate all our efforts toward the probably impossible task of keeping it from spreading, but rather to study the circumstances that, in addition to exposure to the virus, make for the occurrence of paralysis in the exceptional few of those exposed. There are reasons for believing that a difference in those exposed, rather than any difference in exposure, determines whether or not paralysis occurs. Paralysis picks not just any who are exposed, but a certain few. Some of these selectivities may give a clue of the cause of this susceptibility to paralysis, and this appears to be one of the most important things to learn about the disease, because paralysis is the one serious consequence of infection with this virus.

What are the selections that govern paralysis? The frequency of paralysis in those exposed varies in different climates, and also with season in the same locality. There are many persons who are exposed without having the recognizable disease in regions nearer the equator, and this is also true in off-seasons in temperate zones, where infantile paralysis is commoner. This influence of climate and season on the prevalence of the disease suggests that some physiologic process, which fluctuates with climate and season, conditions the response of persons to exposure to the virus.

A reason for believing that some factor in the patient determines the development of the disease on exposure to the virus is its tendency to occur in multiple numbers in some families, not only in brothers and sisters, but in members of successive generations, and in both lineal and collateral lines. This familial frequency is out of proportion to the low incidence of the disease in the general population, and suggests that susceptibility is in some way associated with an inherited quality.

That the disease tends to occur in persons of a certain constitutional type has long been suspected by those who see many cases. The observation, although by no means universal, has nonetheless been made often enough to suggest that children, whose glandular functions regulating growth and development are in some way modified, are more susceptible to paralysis than others.

Again, the virus of infantile paralysis evidently enters the system through the mucous membrane of the upper respiratory tract, and this mucous membrane, when sound, is probably the barrier that prevents the virus from reaching the nervous system. A number of cases of paralysis have followed tonsil and adenoid operations, and this bears out the idea that injury to mucous membranes may let the virus through to the nervous system.

Moreover, there is an impression that infantile paralysis occurs oftener than would be expected on the laws of chance in persons at certain times, when there are known

\*A "Green Lights to Health" broadcast given through Station WAAB by Dr. W. Lloyd Aycock on Wednesday, April 30, and sponsored by the Public Education Committee of the Massachusetts Medical Society and the Massachusetts Department of Public Health.

changes in the mucous membranes due to alterations in hormone secretion. These naturally occurring changes have been reproduced experimentally in monkeys. When these animals are given instillations of the virus in their nostrils, their resistance is seen to be different from that of normal animals. In addition to these experiments it has been found that children who have had infantile paralysis have different glandular secretions as compared with those who have not had the disease.

Thus, from all these studies, we may say that the exceptional occurrence of paralytic infantile paralysis among the many who are exposed to the virus is determined by individual susceptibility which is physiologic in nature and bound up with differences in certain of the endocrine glands. Infantile paralysis therefore, does not present the simple problem of a disease to which we can apply universal preventive measures such as smallpox in which we can vaccinate everybody, or rabies in which we can readily select the few who need vaccination—those bitten by a rabid animal. From the point of view of paralysis infantile paralysis is a disease of limited occurrence, and close attention must be paid to its behavior when the practicability of preventive measures is considered.

These talks are called Green Lights to Health. The green lights in infantile paralysis now seems to be in the direction of studying the question of susceptibility. If we are to be able to pick out the few who are susceptible, to try to understand what makes them susceptible and to learn how to correct their susceptibility in the hope of turning what is for them a distressing disease into what is for most people a harmless immunizing infection. For it may not be feasible to adopt too sweeping or drastic measures for the benefit of a few of the many who are exposed to the virus.

Now that knowledge has extended to the milder infections with this virus we can take some comfort, if an epidemic appears when we remember that over half the cases diagnosed do not develop paralysis, that probably half the patients who do develop paralysis recover entirely and that many of these are so slightly affected that they are not at all handicapped in following any of the ordinary pursuits of life.

## DEATHS

**CHRYSTAL**—MICHAEL H. CHRYSTAL, M.D., of Leominster died July 13. He was in his seventy-fourth year.

Born in North Adams, Dr. Chrystal received his degree from Baltimore Medical College in 1901. He was a member of the surgical staff of the Leominster Hospital and was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow and two sisters survive him.

**SMITH**—ALFRED C. SMITH, M.D. of Brockton died July 15. He was in his seventy-third year.

Born in Capetown, South Africa, Dr. Smith received his degree from Tufts College Medical School in 1898. He was a former president and treasurer of the Plymouth District Medical Society, and a member of the Massachusetts Medical Society, being a member of the Committee of Ethics and Discipline for many years, and of the American Medical Association.

His son survives him.

## NEW HAMPSHIRE MEDICAL SOCIETY

### DEATH

**CHEEVER**—NATHANIEL F. CHEEVER, M.D. of Greenfield died June 15.

He was born in Walden, Vermont, in 1856, graduated from the University of Vermont Medical College in 1883, and had practiced in Greenfield and the surrounding towns since 1884. He was a member of the American Medical Association and of the New Hampshire Medical Society, was prominent in fraternal organizations and held various town offices. He represented Greenfield in the Legislature in 1909-1911.

**KITTREDGE**—FRANK E. KITTREDGE, M.D., of Nashua, died July 8. He was in his eightieth year.

Born in Concord, Dr. Kittredge received his degree from the University of Pennsylvania School of Medicine in 1885. He had practiced in Nashua since 1889 and was one of the founders of the Nashua Memorial Hospital. He was a member of the New Hampshire Medical Society, the American Medical Association, the American College of Surgeons, the American Academy of Ophthalmology and Laryngology and the American Laryngological Rhinological and Otolaryngical Society.

## MISCELLANY

### RÉSUMÉ OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR MAY, 1941

DISEASES	MAY 1941	MAY 1940	FIVE YEAR AVERAGE*
Anterior poliomyelitis	0	1	3
Chicken pox	12	1207	1107
Diphtheria	9	11	1
Dysentery	1284	1373	1211
Dysentery, bacillary	2	15	9
Cerebral measles	640	109	315
Conorrhoea	319	313	393
Lolal pneumonia	209	206	414
Measles	4117	4058	3846
Meningococcus meningitis	8	3	14
Scrub typhus	1479	943	1047
Paratyphoid B fever	12	22	25
Scarlet fever	827	670	905
Syphilis	437	518	473
Tuberculosis pulmonary	333	350	244
Tuberculosis, other forms	34	31	77
Typhoid fever	9	16	6
Undulant fever	158	8	4
Whooping cough	1158	757	684

\*Based on figures for preceding five years

### GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Diphtheria was reported from Acton, 1, Boston, 2, Brookline, 1, Cambridge, 1, Fall River, 2, Revere, 1, Watertown, 1, total, 9.

Dysentery, bacillary, was reported from Waltham, 1, Worcester, 1, total, 2.

Malaria was reported from Winthrop, 1, total, 1.

Meningococcus meningitis was reported from Brockton, 2, Chatham, 1, Fall River, 1, Hardwick, 1, New Bedford, 1, Quincy, 1, Taunton, 1, total, 8.

Paratyphoid A fever was reported from Chariton, 1, total, 1.

Paratyphoid B fever was reported from Cambridge, 1, Foxboro, 1, Lexington, 9, Malden, 8, Needham, 1, Waltham, 1, Worcester, 1, total, 22.

Pellagra was reported from Boston, 1, total, 1.

Septic sore throat was reported from Andover, 2, Beverly, 1, Boston, 8, Fall River, 1, Gill, 1, Merrimack, 2, Milton, 1, Oxford, 1, Scituate, 1, Williamstown, 1, total, 19.

Tetanus was reported from: Dudley, 1; Middleboro, 1; New Bedford, 1; total, 3.

Trachoma was reported from: Boston, 1; total, 1.

Typhoid fever was reported from: Arlington, 1; Boston, 4; Carver, 1; Leicester, 1; Medford, 1; Newton, 1; total, 9.

Undulant fever was reported from: Bridgewater, 1; Gloucester, 1; Leominster, 5; Milford, 1; Newton, 1; Pittsfield, 1; Shelburne, 1; Worcester, 1; total, 12.

German measles, measles, mumps, pulmonary tuberculosis, undulant fever and whooping cough show an increased prevalence, all being higher than the average for the five previous years.

Diphtheria, bacillary dysentery, lobar pneumonia and typhoid fever were reported less frequently than usual, all except the last being below the five-year average.

No cases of anterior poliomyelitis were reported during the month.

Meningococcus meningitis has been gradually increasing, but has not as yet reached the five-year average.

The incidences of chicken pox, dog bite, paratyphoid fever and scarlet fever were at about normal levels.

## NOTES

The following promotions on the faculty and teaching staff of the Harvard Medical School, effective next September, were recently announced: Donald L. Augustine, associate professor of comparative pathology and tropical medicine; William L. Aycock, associate professor of preventive medicine and hygiene; Harry C. Solomon, clinical professor of psychiatry; Charles G. Mixer, clinical professor of surgery; Robert S. Morison, assistant professor of anatomy; Thomas D. Jones, assistant professor of medicine; Aubrey O. Hampton, assistant professor of roentgenology; Arthur T. Hertig, assistant professor of pathology; Jacob Fine, assistant professor of surgery; Harold G. Tobey, lecturer on laryngology; Henry R. Vies, lecturer on neurology; Charles T. Porter, lecturer on otology; George G. Smith, lecturer on genitourinary surgery; Henry S. Bennett and Edward W. Dempsey, associates in anatomy; John L. Oncley, associate in physical chemistry; Mark D. Altschule, Howard F. Root and Eugene A. Stead, Jr., associates in medicine; Charles D. May, associate in pediatrics; Eric Lindemann, associate in psychiatry; John E. Dunphy, Franc D. Ingraham, Champ Lyons, Leland S. McKittrick and Augustus Thorndike, Jr., associates in surgery; and John H. Harrison and Fiorindo A. Simeone, associates in genitourinary surgery.

President Leonard Carmichael of Tufts College has recently announced that a fund, representing a fiftieth birthday present from over two hundred friends to Mr. Joseph F. Ford, a Boston manufacturer, has been turned over to Tufts College Medical School. It will be known as the Joseph F. Ford Student-Aid Fund, and the income will be used to help deserving students to defray the costs of medical education.

## CORRESPONDENCE

### "PRACTICAL ASPECTS OF SURGICAL SHOCK"

To the Editor: Dr. J. Englebert Dunphy's review of the shock problem in the May 22 issue of the *Journal* is neat and timely, but it would be unfortunate if his article were to spread an impression that observation of the pulse and of the arterial blood pressures fails to detect shock early.

Pulse rates were of no value, he and his collaborators have concluded in recently published experiments with barbiturized animals. Their published protocols show

fast control pulse rates, often 100 to 130. Many physiologists use only well-trained animals, to avoid the unnatural experimental conditions of narcosis, and they have shown the normal pulse rate of large dogs to be 60 to 80. Barbiturate narcosis has been shown to raise the pulse rate through sympathetic stimulation. But in any case, the protocols of Dr. Dunphy and his collaborators show rather immediate further elevation of pulse rates of burned or traumatized barbiturized dogs to maximums of 150 to 200 beats a minute. Even in barbiturized dogs, then, the pulse rate seems to react definitively in the early stage of shock. Their conclusion has no basis in fact; let them first show dogs approaching shock with pulse rates below 80.

More unfortunate is their error of calling the pressure recorded by an intra-arterial Ludwig mercury manometer "the blood pressure" in their text and "systolic pressure" in their tables. It is only the integrated mean arterial pressure, that is to say, the mathematical average of the changing pressures in a given artery during the whole heart cycle. Of course they, like everyone else, find that this mean pressure is well maintained throughout early shock, in the compensated stage of "diminished effective blood volume." The same sort of maintenance of mean pressure takes place in us every day when we rise from the lying to the standing position: at the same time the venous return and therefore the cardiac output diminish, the pulse rate rises very slightly, and the pulse pressure (systolic arterial minus diastolic arterial pressure) narrows definitely. Every physician who understands what he is studying when taking a Schneider index knows that he must observe the diastolic arterial pressure and that he should consider the systolic only in relation to it: he speaks of the blood pressures, not of the blood pressure.

Experimentally, investigators of the shock problem must discard the hoary Ludwig mercury column and must learn from physiology texts the meaning of diastolic arterial pressure. The use and necessity of a Huerthle spring-type or better a Hamilton membrane-type manometer deserve stress. It is easy to demonstrate with one of these that as soon as a small fraction—5 to 10 per cent—of the blood volume has been withdrawn, the pulse pressure narrows, usually with a distinct rise in diastolic and maintenance of mean arterial pressure. When small fractions are repeatedly withdrawn, the pulse pressure becomes progressively narrower and finally the mean pressure fails. This simple fact holds both in trained unanesthetized and anesthetized animals. It can be observed in any blood donor. I believe the experimental surgeons' persistent error in using Ludwig manometers should be called to account. Their continued inadequate concept and their thinking in terms of "the blood pressure" should no longer merit attention.

Experimental surgeons have slowly and laboriously gained a fruitful concept of "effective blood volume." This is qualitative at best. Now they urge universal adoption of hematocrit readings and red-cell counts and of falling-drop and plasma-protein determinations. These factors, in different stages and in different types of shock, change in varied directions. They, also, are qualitative when it comes to being interpreted. The surgeons still have to emphasize, perfectly correctly, that "correct appraisal of the condition [of the patient in shock] and the institution of proper replacement therapy are dependent on a careful study of the patient as a whole." Since the laboratory determinations which they recommend are not always reliably done even under the hothouse conditions of the experimental laboratory, and since they must be evaluated in a qualitative manner even by the expert, I urge a wider appreciation of the simple, mean-

ingful and quantitative determinations of the pulse rate and of the pulse pressure and the diastolic arterial pressure—the systolic pressure and the mean pressure are best forgotten. These measurements objectively check the all important clinical observation of the patient, especially his tongue, and the warmth and moistness and color and pulse quality of his extremities. Unlike hematocrit readings and plasma protein determinations, they are available to every practitioner and in every circumstance civil and military.

Physiologists have striven to avoid the qualitative and shifting sands of effective blood volume, albeit they neglect hematogenic, vasogenic and neurogenic types of shock. They do not speak of effective blood volume, but they quantitatively measure cardiac output. They show that during compensated shock the mean arterial pressure is well maintained, but the venous pressure and venous return (or cardiac output) are diminished. They teach that this measurable diminution, not the late drop in mean pressure of uncompensated shock, is the essential pathologic change. Pulse rate times pulse pressure gives an index which is a good serviceable first approximation of the cardiac output. No method of measuring cardiac output is ideal, not even the gas absorption methods or Hamilton's dye method. This last is to be recommended, nevertheless, in all investigations that include blood volume studies, for it can be combined with them easily without loss of accuracy to either measure. For clinical use, a diminishing series of products obtained by multiplying pulse rates by pulse pressures is an early, accurate measure of diminishing effective blood volume and impending shock. It can be interpreted in only one way unlike hematocrit readings and plasma protein determinations, it applies to shock of every stage and of every type and it requires only an attending physician with a watch and a sphygmomanometer.

Future study of shock ought to elucidate in what parts and to what degree the circulation is inadequate. The body extremities can be studied simply with oncometers, but conditions are easily vitiated by changes of body temperature. Visceral circulation studies are very painstaking and require trained unanesthetized animals and Rein's *Thermotromuhr*. These methods will teach us just how much various parts of the body are made to sacrifice their needed circulation to the end that the delicate brain cells and their jealous guardian the carotid sinus, receive a proper supply of oxygen and glucose, perhaps the kidney will be found to assert itself through its chemoregulators. As yet, we are ignorant of how much and for how long the various parenchymatous and vascular tissues can undergo oxygen deprivation and other metabolite insults. Real understanding of shock cannot come in advance of such studies.

Meanwhile the understanding observation of pulse rates and of blood pressures, both pulse and diastolic, deserves not less but rather more stress. If these objective measures have not been helping all of us, the fault is not in them but in ourselves.

ROBERT J. KINNEY, MD

512 East State Street  
Ithaca, New York

The above letter was submitted to Dr Dunphy, and the following reply was received:

To the Editor: Theoretically it is true, as Dr Kinney points out, that a diminishing series of products ob-

tained by multiplying pulse rate by pulse pressure is a measure of diminishing effective blood volume and impending shock. Perhaps it deserves more rather than less attention.

However, the tide of my review was Practical Aspects of Surgical Shock, and in actual practice, determinations of the pulse rate and pulse pressure are quite unreliable as a guide to fluid requirements in individual patients. To take a practical example during the course of some recent studies, 1220 cc of blood was removed in thirteen minutes from a volunteer subject. This constituted an actual reduction of the blood volume of over a quarter of the estimated total. Before removal of the blood, the pulse rate was 60, and the blood pressure 114 systolic, 75 diastolic. Four minutes after removal of the blood the readings were pulse 84 and blood pressure 110 systolic 80 diastolic. By no stretch of the imagination could these figures or even the difference between these figures be construed as evidence of a serious reduction of the blood volume. To a surgeon however, the loss of over a liter of blood may be of considerable importance and he must attempt to anticipate and correct such losses before significant alterations of the pulse and blood pressure occur.

This experiment is not a theoretical or hypothetical problem. The same thing occurs daily in surgical practice. To cite another example a patient recently entered this hospital seventeen hours after a free perforation of a duodenal ulcer. At the time of admission he was in evident peripheral vascular collapse. The pulse rate was 140 and the blood pressure could not be obtained. Following the administration of morphine and 1000 cc physiologic saline solution in the Emergency Ward the pulse rate was 110 and the blood pressure 105 systolic, 70 diastolic. Now a pulse rate of 110 and a blood pressure of 105 systolic 70 diastolic are not in themselves indicative of shock. Such levels are commonly observed under Avertin or spinal anesthesia without having any grave prognostic significance. Therefore, it is important that the hematocrit reading in this particular patient was 75 per cent and the serum protein 4.5 gm per 100 cc indicating an enormous reduction of the blood volume. Nearly 2000 cc of blood and plasma were required to restore this patient's hematocrit reading and serum protein level to normal, at the end of which time he had improved to such a degree that he withstood operation without difficulty. Over 2000 cc of fluid with a high protein content (3.8 gm per 100 cc) was found in the peritoneal cavity. Is a pulse rate of 110 and a blood pressure of 105 systolic, 70 diastolic, indicative of such an enormous loss of fluid?

In closing it is important to emphasize that determinations of the hematocrit and the plasma protein are quite simple procedures, readily done by any physician or technician capable of doing a red-cell count. The only expensive equipment needed is a good centrifuge. Finally, it should be stressed, as I emphasized in my review, that no laboratory procedures can supplant an accurate and careful clinical appraisal of the patient in shock. Examination of the pulse and blood pressure are procedures that will never be discarded and that often provide information of great value, but it is no longer correct to consider them infallible guides to the state of the circulation.

Boston

## REPORT OF MEETING

## NEW ENGLAND PEDIATRIC SOCIETY

At a meeting of the New England Pediatric Society, held on April 30 at Longwood Towers, Brookline, Dr. Samuel Levine, professor of pediatrics at Cornell Medical College, spoke on "Some of the Physiologic Peculiarities of the Premature Infant."

Dr. Levine began his talk by stating that the transition from intrauterine to extrauterine existence demands adaptations, and that premature infants make these adaptations less successfully, owing to their inadequate physiologic development. Charts were then shown of the causes of infant deaths: prematurity led, with 47 per cent, and birth injury and congenital malformations followed, with 14 and 10 per cent, respectively. The great preponderance of prematurity over any other single cause of infant death left little more to be said about the importance of the topic of discussion. It was further pointed out that even more significance should be attached to infant deaths as a whole, because of the present decline in birth rate.

The first physiologic system discussed by Dr. Levine was the respiratory apparatus. In this respect, it was shown that the premature infant was heavily handicapped, since five other systems may contribute to respiratory distress: the nervous system, by having a poorly developed gag and cough reflex; the vascular system, by decreased development of capillary circulation and thus more danger of atelectasis; the skeletal system, by weakness of the thoracic cage; the blood, because lowered fetal hemoglobin gives poor oxygen intake; and finally, the connective tissues, owing to lack of development of elastic tissues in the pulmonary vessels. The chemical stimulation of respiration in the premature infant is less sensitive than in the fully developed infant, the speaker reported; he showed a series of charts of his experiments in varied oxygen and carbon dioxide mixtures, which supported his statement.

Another very serious handicap to the premature infant, as compared with the full-term infant and the infant a few days after birth, was shown to be the delayed development of the capillaries of the medulla and lungs. Many slides were shown in which the capillaries, clearly demonstrated by the injection of dyes, were markedly inadequate in the medullae and lungs of premature infants. A well-graded series of these slides illustrated the speaker's next contention—that the capillary development of the lungs and medulla is proportional to the birth weight of the baby. The elastic tissue in the blood vessels was also found to be proportional to the birth weight of the infant.

The subject of bodily temperature was then taken up, and here again the premature infant was said to be badly handicapped because of a combination of several factors. Owing to incomplete muscular and systemic development, there is, first of all, low total-heat production. This is enhanced by the slow metabolism and consequent general inactivity of the infant. Inadequate use of calorogenic hormones (thyroxin and adrenalin) was also reported in premature infants, as well as poor sweating mechanisms on exposure to heat. One of the chief difficulties in heat regulation met by the underdeveloped infant was said to be due to the lack of proportion of surface area to body weight, the surface area being in considerable excess, and thus increasing loss of body heat. This, coupled with the insufficient amount of subcutaneous fat of the premature infant, dangerously impedes the retention of body heat. Dr. Levine showed results of his tests of heat conduction

in tissues of infants. These revealed that in spite of inadequate elastic tissues in the capillary walls, the premature infant had adequate heat conduction, better even than that of an adult, and hence that poor control of body heat was not due to a sluggish vasomotor system but to the large surface area and to the poor development of subcutaneous fat.

A study of water balance disclosed that the premature infant has an appreciable lowering in fluid output through the skin and lungs, as compared with the normal infant. A relatively greater burden is thrown on the kidneys. It was further found that the urea clearance is lower in premature infants, and increases with growth. The cause of the lowered urea clearance was found to be the decreased patency of the glomerular capillaries and the decreased development of epithelium of Volkmann's capsules. Impairment of kidney function was thus added to the list of handicaps to be met by the premature infant.

In the gastrointestinal tract, there are the problems of poor sucking, poor secretion of enzymes and, especially, poor absorption of fats. Premature infants were found to excrete more than the normal 5 to 10 calories per kilogram. However, carbohydrates and proteins were found to be metabolized satisfactorily, as evidenced by normal respiratory quotients and normal values for nitrogen absorption. This led to the practical suggestion that, to make premature infants increase weight most rapidly, fats should be replaced by carbohydrate and protein, instead of the usual custom of merely increasing the total number of calories in the diet.

There are several reasons for anemic tendencies in premature infants, such as deficient antenatal iron and copper storage, increased rate of neonatal blood destruction, incomplete development of respiratory enzymes and high incidence of digestive upsets. Hemorrhagic tendencies are present, owing to low prothrombin content of the blood and to weak capillaries, which are weakened further by poor elastic tissue.

There are several rachitic tendencies: reduced calcium and phosphorus storage, which is increased still more by the necessity of keeping premature infants indoors, rapid rate of growth, with a resultant drain on bone and other tissues, and decreased absorption of fats and fat-soluble vitamins.

Finally, Dr. Levine reported that vitamin C had been shown to have a specific effect in protein metabolism. As evidence of incomplete protein metabolism, he was able to demonstrate phenylalanine and tyrosine in the urines of premature infants; these substances were found in larger amounts when cow's milk was being used, because of the relatively high protein content of cow's milk. The oral administration of vitamin C, in the form of 100 to 500 mg. of levoascorbic acid, caused the disappearance of phenylalanine and tyrosine from the urine; hence, he concluded that it is advisable to administer vitamin C to premature infants soon after birth, especially if cow's milk is being used.

## BOOK REVIEWS

*Strange Malady: The story of allergy.* By Warren T. Vaughan, M.D. 8°, cloth, 268 pp., with 23 illustrations. New York: Doubleday, Doran and Company, Incorporated, 1941. \$3.00.

Any book that sets out to interpret science for the layman is as difficult to write as it is to review. How much knowledge should the writer expect his public to possess? How is he to present his subject so that it gives

balanced understanding? The reviewer, if he is a specialist in the same field, may quite justifiably think that some things are oversimplified and others not sufficiently explained.

Patients with allergy will get some understanding of their malady from Dr Vaughan's book. They will not, however, get a balanced point of view. Little space is given to the straightforward routine methods of study and to the simple, easily discovered environmental allergens that are the cause of the majority of symptoms. Perhaps to make the book more interesting, much emphasis is given to the dramatic, the rare and the complex.

There can be few patients so sensitive to nickel that symptoms of contact dermatitis occur from the amount of nickel that might be left in the skin from a needle used to give an injection hypodermically. Nor are there many patients who, having indigestion following the eating of chicken, can be relieved of their discomfort by enemas of chicken broth. Dr Vaughan describes the case of a patient allergic to grapes who had a rise in blood pressure of thirty to forty points if he drank a Martini cocktail, but a fall in blood pressure when he drank a Scotch highball. Another patient had sick head aches when he ate veal less than six weeks old. And still another was said to be so sensitive to sage pollen that he had hay fever if he ate mutton taken from an animal that had eaten sage.

The most fantastic note of all concerns a sailor who had an eagle tattooed on his chest. Cinnabar, which contains mercury, had been used for the eyes. When the sailor used mercury antiseptics, the eyes of the tattooed eagle were supposed to have become sore and eczematous. Why they were not continuously eczematous if the patient was really sensitive to mercury is not mentioned. And what the mercury antiseptic did to the lesion on which it was used is also not explained. Stories of this type will raise the readers' eyebrows oftener than they will carry conviction.

These examples are not culled from the book to discredit Dr Vaughan, whose reputation stands on a firm basis, but merely to show how dangerous it is to write a popular work unless one exercises great restraint. The lay reader would get some idea of the allergic processes but his picture of what an allergist does would not in any sense be a true one. It is a pity that the author's sense of the dramatic so overshadowed his scientific caution. Many of the examples given would be caviar not only to the general public but also to most practicing allergists.

*Studies on the Human Thyroid in Iceland* By Julius Sigríðsson 8°, paper, 130 pp., with 21 tables and 10 figures. Reykjavík: Premsmiðjan Edda H. F. 1940 6s

This book will be of interest to those who are concerned with problems of the thyroid gland. The size of the normal thyroid gland forms the subject of one chapter. Figures are given for the length, breadth, thickness and weight of the thyroid gland with comparative values for Germany and Iceland. The author concludes that the weight of the gland is a most significant feature. It is noted that the average weight of thyroid glands from Iceland and Japan is low.

The chapter concerning the history of iodine and the early use of iodine in the treatment of goiter is excellent. A discussion of methods for iodine analysis in this rod tissue is included, together with the method that the

author employed in his studies. The proportional and total iodine content of thyroid glands from Iceland is compared with that of glands from other districts. The values for Iceland are generally lower and compare with those found in Japan.

According to the author's results, the size of the thyroid gland increased when acute infectious processes had preceded death, in other diseased conditions, there did not appear to be any significant change.

The chapter on hyperplasia of the thyroid gland and its relation to iodine content is the best section of the book. This includes an excellent analysis of present theories, based on available experimental data, and emphasizes the viewpoint that hyperplasia of the thyroid gland indicates a relative iodine insufficiency. Whereas Marine has stated that the iodine content of the thyroid gland per gram weight is the important factor in the presence of colloid or hyperplastic thyroid tissue, the author believes from his studies that the total iodine content of the thyroid gland is a more significant figure. Since, in Iceland, the thyroid glands are smaller, the iodine content is less, and colloid goiter is rare, this difference in viewpoint is obvious.

*Surgical Anatomy of the Head and Neck* By John Finch Barnhill, MD, LL.D., and William J. Mellinger, MD. Introduction by Paul S. McKibben. Second edition, rearranged and revised. 4°, cloth, 773 pp., with 431 illustrations. Baltimore: Williams and Wilkins Company, 1940 \$15.00

The important change in the second edition of this work consists in the removal of the illustrations from a previous separate section, and their placement throughout the text where they can be consulted with ease.

The book furnishes a good comprehensive survey of the surgical anatomy of the head and neck, particularly from the viewpoint of the otolaryngologist. The material is covered in much greater detail than is usual in texts on general surgical or applied anatomy.

Although the conversational tone of the book, its arrangement about regional dissections and its rough but original drawings prevent the work from being concise, they do make it stimulating and rather charming.

*Diagnosis and Treatment of Menstrual Disorders and Sterility* By Charles Mazer, MD, and S. Leon Israel, MD. 8°, cloth, 485 pp., with 108 illustrations. New York: Paul B. Hoeber, Incorporated, 1940 \$6.50

It would be difficult to find a more comprehensive book than this on the subject of sterility and endocrine disorders peculiar to women. Not only are the abnormal manifestations of endocrine function as they apply to menstruation fully described and treatment suggested, but at the beginning of the book there are four chapters on the normal endocrine relations. The section on sterility is very complete, and when necessary, the description of the endocrine factors is repeated. In the sterility section, also, there is an interesting chapter that deals with habitual abortion. The diagnosis and treatment of male sterility and the technique of semen examination are included. Other tests, such as the tube test, endometrial biopsy and so forth, that are useful in the diagnosis of sterility are also described in detail.

There are many excellent illustrations and a well arranged index, a large bibliography is appended to each chapter.

Two criticisms should be made, although neither is particularly serious. The first is that, although a great deal of the material dealt with by the book is highly controversial, the authors tend to be somewhat dogmatic, and anybody using it must realize that the last word has not been said on many of these subjects. The other criticism is that the chapters on male sterility are written by Dr. Charles W. Charny, which seems to indicate that Drs. Mazer and Israel do not themselves check the husbands of their patients. The reviewer is convinced that an adequate picture of sterility in a couple can be obtained only when one man does the work-up on both partners.

In general, however, this book can be recommended highly, although its price will probably keep it off the shelves of anybody but the specialist in this field.

*Methods of Treatment.* By Logan Clendening, M.D., and Edward H. Hashinger, M.D. Seventh edition. 8°, cloth, 997 pp., with 138 illustrations. St. Louis: The C. V. Mosby Company, 1941. \$10.00.

This is the seventh edition of a text on treatment in internal medicine, first published in 1924. It is a summary of therapeutic procedure in one compact volume presented in the concise, lucid style characteristic of its senior author, Logan Clendening. Based both on material gathered discriminately from the ever-changing medical literature and on the wide clinical experience of the collaborating authors, all specialists in their respective fields, this work should be valuable to the general practitioner. The first part is devoted to methods of treatment in all its aspects, the second to their application to particular diseases. The work is well illustrated.

*Man's Greatest Victory over Tuberculosis.* By J. Arthur Myers, Ph.D., M.D. 4°, cloth, 419 pp., with 31 illustrations. Springfield, Illinois: Charles C Thomas, 1940. \$5.00.

This book deals chiefly with the remarkable accomplishments and progress made by veterinarians in the prevention of tuberculosis in cattle. Dr. Myers's main thesis is that a positive reaction to the tuberculin test signifies the presence of tuberculous lesions. Thus he extols the veterinarians for their steady insistence on the tuberculin testing of all herds and the elimination of the positive reactors. That the veterinarians have been successful in their task is attested by the fact that the entire nation is now an accredited area, which means that the number of cattle reacting to tuberculin is less than 0.4 per cent. Whereas in 1917 only 20,000 cattle were tested, 25,000,000 tuberculin tests were carried out in 1935.

This book consists of twenty-six chapters, very well written in a remarkably easy and fluent style. Each chapter has a good summary. The last chapter, entitled "Lessons for Physicians in Human Medicine," is apparently the real reason for the writing of the book.

The author, who has always been in the forefront of the fight against tuberculosis, has been the advocate of segregation and the more aggressive treatment of "open" cases of pulmonary tuberculosis. He has always been the opponent of those recommending immunization against tuberculosis with attenuated organisms (BCG). He stresses the fact that immunization has accomplished nothing so far as the prevention of tuberculosis in cattle is concerned, and that good results have been obtained only after all the positive reactors have been eliminated from the herd. Thus he deplores strongly the facts that physicians have done almost nothing to provide quarantine for

tuberculous persons, that they have allowed such persons to enter this country without adequate examination, and also that there is no ban on intercounty or interstate travel.

The author points out that a person reacting to tuberculin has definite tuberculous lesions, and hence has tuberculosis. Just what steps we should take in the prevention or treatment of such cases he omits to state. He apparently considers the preventorium to be of little or no value. He wishes only to direct attention to these matters, leaving their correction to the proper health authorities.

Veterinarians, particularly, should find this book interesting and instructive. In addition, it contains much material that should aid physicians in dealing with the many problems of human tuberculosis.

*A Handbook of Elementary Psychobiology and Psychiatry.* By Edward G. Billings, M.D. 16°, cloth, 271 pp. New York: The MacMillan Company, 1939. \$2.00.

This little book represents an attempt to summarize psychiatry from the psychobiologic point of view. The author has spent some time at the clinic of Dr. Adolf Meyer at Johns Hopkins, has acquired an understanding of his point of view and terminology, and has added to this the experience of working at the Psychiatric Department at the University of Colorado.

The chapters dealing with psychiatric examination procedures and with the descriptive material of the psychotic syndromes are by far the best. Brief and succinct methods are presented for obtaining the complete psychiatric history and mental status. The types of disturbed behavior encountered in psychiatric work are well described. It is in these that the reviewer believes that the major contributions of the psychobiologic school have been made. The emphasis on a good clinical study of the patient and on a careful and helpful observation of the patient is most creditable.

The chapter on psychobiology is an understandable presentation of an important point of view in psychiatry. It is well done, and its limitations are the inherent limitations of that approach and its terminology. The chapter on psychotherapy is clear, but little reference is made to data indicating the therapeutic value of the approaches suggested. Any therapeutic procedure, logical as it may seem, is only of interest and theoretical value unless it is supported by a series of cases proving its validity. The selected readings in Part V represent the basic writings in the field of psychiatry.

This book has value for the student, the internist, the surgeon and the psychiatrist. It fulfills the purpose of the author.

*Diseases Transmitted from Animals to Man.* By Thomas G. Hull, Ph.D. Second edition. 8°, cloth, 403 pp., with 45 illustrations. Springfield, Illinois: Charles C Thomas, 1941. \$5.50.

The nexus of bacteriology and clinical medicine is very adequately represented in the study of diseases common to animals and man. Their manifestations as disease forms, the distinctive immunologic variations and the manner of spread are all important to those seeking knowledge in this field. This volume in a compact form offers a wealth of information of this nature. The list of diseases is too long to enumerate, and each is prefaced by brief historical data of great interest.

The type and format are so outstanding as to merit distinct praise.

## A FRACTIONAL BROMSULFALEIN TEST TO DETERMINE LIVER DAMAGE IN THE NONJAUNDICED PATIENT\*

EMMANUEL DEUTSCH, M.D.†

BOSTON

**D**ESPITE the large amount of work that has been done on the functions of the liver during attacks of jaundice, very little attention has been paid to the problem of residual liver damage after the patient has recovered. This is probably because the available methods have failed to show variations from normal in the majority of cases. During the last three years, 50 patients with disease of the liver have been studied in an effort to appraise the amount of residual liver damage, during and after convalescence, by frequent hippuric acid excretion, urinary urobilinogen, icteric index, total, free and ester cholesterol and lipid phosphorus determinations<sup>1</sup> and modifications of the bromsulfalein-excretion test.

Bromsulfalein has been in use for the last fifteen years and is generally considered the most satisfactory dye for determining liver function. Mills and Dragstedt<sup>2</sup> found that the mode of excretion of intravenously injected bromsulfalein is through the reticuloendothelial system, since blocking of these cells with India ink results in marked retention of the dye in the blood stream. Obstruction of the bile ducts does not impair the removal of bromsulfalein to the extent that it impairs bilirubin excretion.<sup>2</sup>

These authors have observed that removal of the dye in dogs appears to occur in two phases.<sup>2</sup> In the first five minutes after injection, 85 to 95 per cent of the dye is removed from the blood stream. A secondary or subsequent phase of varying length occurs after this five-minute interval, during which the remainder of the dye is excreted.

### METHODS AND MATERIAL

The hippuric acid excretion was determined by the method of Quick.<sup>3</sup> Normal human beings ex-

crete 2.5 to 3.0 gm. within four hours of the administration of 6.0 gm. of sodium benzoate. Urobilinogen in the urine was determined by the procedures of Watson<sup>4</sup> and Wallace and Diamond.<sup>5</sup> Normal persons excrete up to 4 mg. in twenty-four hours by the Watson method and show urobilinogen present in a 1:16 dilution by that of Wallace and Diamond.

Using the Rosenthal<sup>6</sup> technic, 2 mg. of bromsulfalein per kilogram of body weight was injected intravenously. A control blood specimen was taken just before the injection. One-half hour later, a specimen was obtained, rendered alkaline and compared with color standards.<sup>7</sup> Since it soon became apparent that patients only recently recovered from severe attacks of jaundice showed no retention of the dye after thirty minutes, a modification of technic was tried. Bromsulfalein levels in the plasma were observed at intervals of two, five and fifteen minutes. The two-minute sample showed such high levels in normal subjects that it was discontinued. In 10 normal patients at the end of five minutes, bromsulfalein retention was never in excess of 60 per cent, and the fifteen-minute sample rarely showed more than 5 per cent retention of the dye.

Other investigators have demonstrated the value of the fractional bromsulfalein test, although it has never come into common use. Rosenthal and Bourne,<sup>7</sup> using a fractional bromsulfalein test and the Wallace and Diamond<sup>5</sup> method for urobilinogen in urine on patients following various types of anesthesia, showed that a disturbance in function could be demonstrated with the bromsulfalein test long after pigment metabolism had returned to normal.

MacDonald<sup>8</sup> described a fractional bromsulfalein test using 2 and 5 mg. of dye per kilogram of body weight and taking blood specimens every

\*Watson method

†Recovery in the cases of chronic cirrhosis means recovery from the attack of acute necrosis

five minutes for thirty-five minutes. The resultant curves are similar to those given here, but such frequent tests seem hardly necessary.

During this study, no effort was made to perform bromsulfalein-excretion tests during jaundice, — with the exception of cases of hemolytic anemia exhibiting jaundice, — since it has previously been shown<sup>9, 10</sup> that the retention of the dye closely parallels the retention of bile.

In the 60 patients included in this study, the diagnoses were as follows: acute infectious hepatitis, 10 cases; acute toxic hepatitis, 16 cases; chronic cirrhosis, 23 cases; hemolytic anemia, 3

Figure 1 represents the course of 12 cases of acute hepatitis of approximately two or three weeks' duration followed by recovery. It indicates the time relation between the various liver-function tests. Improvement occurred first in the ester fraction of the total blood cholesterol, then in the hippuric acid excretion and finally in the bromsulfalein retention. The initial rise in urobilinogen output early in the disease was followed by a drop associated with diminished bile in the bowel. After four to seven days of clay colored stools, a brown stool appeared at the time of clinical improvement. About two days later, there was a

FIGURE 1 A Composite Chart of Serial Liver-Function Tests in 12 Cases of Acute Hepatitis with Recovery

cases; obstructive jaundice, 3 cases; biliary fistula, 1 case; essential lipemia, 1 case; gall-bladder disease, 3 cases

### RESULTS

In Table 1, the results are given for 73 tests in 50 patients with disease of the liver in whom more than one type of liver-function test was performed. Fractional bromsulfalein tests in 9 patients, or 18 per cent, showed abnormal retention when other tests were normal. Of these, 4 were acute cases (Cases 6, 7, 10 and 16); 3, cirrhoses (Cases 27, 30 and 39), and 2, obstructive jaundice (Cases 43 and 44). In Case 7, the bromsulfalein test still showed retention—90 per cent at fifteen minutes—five months after complete disappearance of the jaundice. In a case of beriberi heart disease (Case 38), the serial hippuric acid excretion was below normal, with a normal bromsulfalein excretion.

In 24 per cent of the patients, both the bromsulfalein retention and the hippuric acid or urobilinogen excretion were abnormal. In 58 per cent, both were normal.

secondary rise in the urinary urobilinogen that was usually higher than the first rise and sometimes persisted for two weeks. The interval between the first appearance of a brown stool and the abnormally increased urobilinogen excretion was quite variable, depending on the degree of liver damage. In a case of acute hepatitis lasting six to eight weeks, this interval may be ten days or more. This phenomenon might be due to a deficit in urobilinogen absorption by the liver.

A study of bromsulfalein excretion in 10 normal persons showed, in contrast to previous results in dogs,<sup>2</sup> that the dye retention at five minutes amounted to only 50 per cent on the average and never exceeded 60 per cent. The normal human being usually shows no more than 5 per cent retention at fifteen minutes.

Most patients recovering from acute diffuse liver damage show abnormal retention of bromsulfalein in both the early and late phases, improvement occurring first in the late phase. In this same type of case, although the fifteen minute specimen may show dye retention within normal limits, the five minute sample may show an abnor-

mally high value, describing a convex curve, and so indicate residual liver damage (Fig. 2). Results of this sort occurred twice in Case 4 and once in Case 7.

In chronic liver disease (Cases 20, 22, 27, 29, 30, 32, 33, 36 and 39), the early removal of the dye followed the pattern of normal persons, whereas the late phase was markedly impaired.

In a small group of cases of residual liver damage receiving sulfonamide therapy, falsely positive Wallace and Diamond tests for urobilinogenuria were obtained in about half the cases, owing to

FIGURE 2. Normal and Abnormal Bromsulfalein-Retention Curves.

The percentage of retention is plotted against the time in minutes, following the intravenous injection of 2 mg. of bromsulfalein per kilogram of body weight. Note that the abnormal curves are convex.

chemical union of the sulfonamide and Ehrlich's aldehyde in the presence of an acid. In another small group of early to moderately advanced cirrhoses, normal levels of urobilinogenuria were noted in the presence of brown stools. In both types of cases, the fractional bromsulfalein test was of considerable help in distinguishing acute from chronic liver damage.

In Figure 3, the results are given for a fatal case of hemochromatosis (Case 20), which showed improvement in both the icteric index and ester cholesterol percentage during the course of the illness. During protamine insulin therapy, the hippuric acid excretion showed a slight improvement, but the patient shortly became incontinent, and it was therefore impossible to use this test. A fractional bromsulfalein test showed a curve characteristic of chronic liver damage. The patient became progressively worse and died five days later. Autopsy showed the typical findings of hemochromatosis.

In some patients, the hippuric acid excretion remains low at a time when the bromsulfalein

test is normal (Cases 22, 37, 38 and 48). A combination of these two tests is always better than either alone.

Two cases of congestive heart failure, pulmonary infarction and jaundice deserve discussion, although they are not included in this series. In spite of multiple tests, there seemed to be no way of determining the degree of liver damage because of the disturbance of circulation and its effect on function tests. At present, it is questionable whether there is any way of evaluating the state of the liver in the presence of circulatory failure associated with pulmonary infarction. One case showed disease of the coronary artery, with multiple pulmonary infarcts and with an icteric index of 80, and normal values for total and ester cholesterol and lipid phosphorus. Four hippuric acid excretion tests in the last three weeks of this patient's life were all below 1 gm. The second case of congestive failure was one of rheumatic heart disease and pulmonary infarction, with jaundice. Bile was absent in six urine specimens. The icteric index was 60, urobilinogen in the urine by the Wallace and Diamond method was repeatedly present in a dilution of 1:64, the hippuric acid excretion remained less than 1 gm., and the

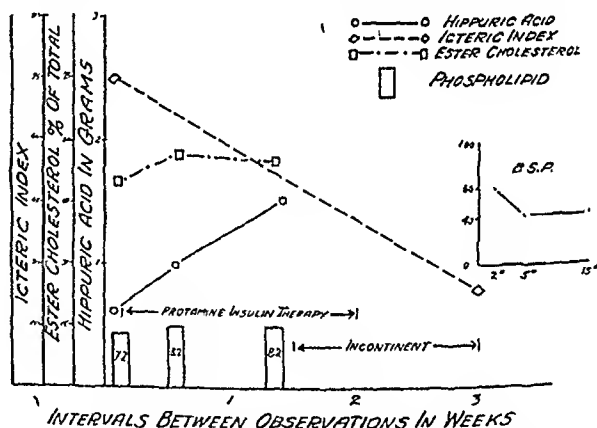

FIGURE 3. Liver-Function Tests in a Fatal Case of Hemochromatosis, with Acute Hepatitis.

fractional bromsulfalein showed 70 per cent retention at the end of five minutes, 40 per cent at fifteen minutes, 20 per cent at thirty minutes and 10 per cent at one hour.

In both cases, the elevated icterus is interpreted as being due to hemolysis associated with pulmonary infarction. From the delayed general circulation time associated with congestive heart failure, it may be assumed that there is some degree of impairment of the renal circulation—hence, the low hippuric acid excretion. With a slow circulation time, poor mixing of the intravenously injected dye may be present for fifteen minutes or more after injection.<sup>11, 12</sup> The fact that two

liver function tests and the icteric index may be disturbed by an extrahepatic process does not mean that these tests are worthless, but rather that they are only of value when used with good clinical judgment. It is fortunate that an estimate of hepatic function in the presence of congestive heart failure and pulmonary infarction with jaundice is not often necessary.

Another case, that of a failing nonjaundiced seventy-year-old patient (Case 8), was studied because of possible liver damage. Her downhill course could have been ascribed to generalized arteriosclerosis, hypertension and cardiovascular syphilis. With a normal circulation time, the bromsulfalein excretion showed 80 per cent retention after five minutes, and 30 per cent after fifteen minutes. Only 1 gm of hippuric acid was excreted. The two latter findings were the only laboratory evidence of hepatic insufficiency. The icteric index was 5, and the determination of the twenty-four hour urobilinogen excretion in the urine was within normal limits. At postmortem, the liver showed healing acute yellow atrophy.

#### COMMENT

From this study, it is evident that a certain small percentage of previously jaundiced patients show abnormal retention of bromsulfalein in the blood stream for periods varying from several weeks to several months following recovery. The abnormality is best revealed by a study of the serum at intervals of five and fifteen minutes rather than the customary thirty minute period, since the longer interval usually shows a normal result. A convex curve indicates residual damage even when the fifteen minute specimen shows no retention.

Soffer and Paulson<sup>12</sup> have shown that the bilirubin excretion test is a better test of residual liver damage than the half hourly bromsulfalein test. I have had no experience with the bilirubin test because of its expense, but it would be of interest to compare the bilirubin and fractional bromsulfalein tests in the same patients. Another advantage of the fractional bromsulfalein test is that its performance requires only fifteen minutes, compared with four hours for the bilirubin test.

A discussion of the hippuric acid excretion test on a similar series of cases has already been given in a previous report,<sup>1</sup> so that it requires no further comment.

#### CONCLUSIONS

A modification of the routine bromsulfalein test has been tried and includes the collection of

specimens at five and fifteen minutes. In a small group of patients, residual liver damage may be detected for periods varying from several weeks to months after jaundice has subsided. In 50 cases in which other liver function tests were used, the fractional bromsulfalein test showed abnormal function in 18 per cent when the other tests gave normal values.

A combination of the fractional bromsulfalein and the hippuric acid test is preferable to the use of either alone.

The test was not affected by variations in hydration or by kidney disease. In 3 cases of hemolytic anemia with jaundice, approximately normal results were obtained. The short time required for the fractional test is a distinct advantage.

Congestive heart failure, with its accompanying poor circulation time, makes the results of this fractional test unreliable, because of the prolonged mixing time of the dye in the general circulation, and also confuses the hippuric acid test, because of poor renal function.

Since this paper was submitted for publication, an article by Lucin and Aggeler (*Am J M Sc* 201:326-340, 1941) has appeared in which the rose bengal test has been modified in much the same manner as suggested here for the bromsulfalein test, and in which the new method is compared with the hippuric acid test.

## THE MANAGEMENT OF A BLOOD BANK AT THE MASSACHUSETTS MEMORIAL HOSPITALS\*

FRANK E. BARTON, M.D.†

BOSTON

AT a recent clinical meeting of the Boston Surgical Society, considerable interest was shown in the technical management of the blood bank at the Massachusetts Memorial Hospitals. The questions and discussions arising in that demonstration prompted the writing of this paper. No attempt is made to review the history of this subject. A recent survey of the literature on blood banks, with an excellent bibliography, is presented by Douglass.<sup>1</sup>

There are very few active blood banks in New England. The reason for this may be the fallacy that the management of a bank requires the services of several full-time technicians, as well as the expenditure of large sums of money. I shall endeavor to prove that this idea is wrong.

A blood bank must have concrete reasons for its existence and demonstrable evidence of its value. The experience of the Massachusetts Memorial Hospitals is that a blood bank provides immediate availability of blood of various types, a safe blood from the standpoint of the transmission of syphilis, an economical blood (the cost of our transfusions has been materially reduced), a means for the collection of plasma (our outdated blood is converted into and stored as plasma), a lightening of the labors of the visiting staff and interns, and an increased efficiency in collecting blood. Furthermore, it places the responsibility of all transfusions on a director and his associates.

The blood bank at the Massachusetts Memorial Hospitals is made up of two component parts: placental blood bank and adult blood bank.

The placental blood bank was described in a previous article.<sup>2</sup> The bank was instituted in March, 1938. Since the development of the adult blood bank, the placental blood has been used for only two purposes: first, as a source of blood for newborn babies and pediatric cases and, secondly, as a source of blood for plasma.

The management of the adult blood bank is described in detail because of the many requests for this information from hospitals throughout New England.

### PERSONNEL OF THE BLOOD BANK

*Director.* A staff member interested in the subject of transfusion assumes the entire responsi-

bility. He selects and supervises the other members of the transfusion service and manages the blood bank. The director should also stimulate research and progress in regard to transfusions and blood banks.

*Operator.* The operator or his alternate physically examines all donors and personally performs all venepunctures for the collection of the blood. In this way, an efficient technic is developed.

*Technician.* A technician has been chosen to specialize in the work of the blood bank. She is a member of the routine laboratory force. The technician is a full-time laboratory worker, and although the duties of the blood bank are her primary interest, she is available for other work. Her duties consist in making hemoglobin determinations and complete blood counts on all donors and personally securing the samples of blood for serologic tests and typing; after collecting the samples, she personally completes their analysis and is responsible for recording all results on the various tags and cards. She also sees that all outdated blood is forwarded to the laboratory for siphonage, and that the plasma is returned to the refrigerator. At the most, this requires three hours a day.

*Running nurse.* The running nurse is a graduate nurse assigned to the two examining rooms where the clinics for the collection of blood are held. Her station at the clinic is permanent. She has, of course, many other hospital duties, but the blood bank is her chief responsibility. She is schooled in the technic, and it is her duty to see that all apparatus used in the collection of blood is in working order. She prepares the donor, and secures the history and permits before blood is taken.

*Supervising nurse.* The supervising nurse is a graduate and a member of the training-school office. She is responsible for all dispensing of blood: house officers are not permitted to remove blood from the bank without her permission during the day or without that of the supervisor of nurses on duty at night. It is her duty to see that the blood nearing the outdated period is dispensed first. Each day, the supervisor checks the refrigerator for temperature, and places on the upper shelves the bloods that have been liberated by completed serologic tests and typing. She tests all bloods for time limits, keeps the filing system in order, no

\*From the Department of Surgery, Massachusetts Memorial Hospitals.

†Instructor in surgery, Boston University School of Medicine; visiting surgeon, Massachusetts Memorial Hospitals.

tifies the cashier when a patient is to be discharged and has not met his obligation to the bank, and prompts the interns to secure donors for patients who have been given blood but have replaced none in the bank. Briefly, the supervisor keeps the bank solvent, and is responsible only to the director.

#### COLLECTION OF BLOOD

The two-unit system is used for the blood-collecting clinic: in one room the donor is questioned and examined, and in the other the blood is collected.

*Room No. 1.* In the history, special emphasis is placed on exanthemas, syphilis, malaria, allergy, tuberculosis, and the time of the last meal and the last transfusion. The donor is prepared on the operating table, with the arm extended on an arm board.

In addition to physical examination, which includes examination of the throat, skin and lymph nodes, the blood pressure, pulse and temperature are taken and a hemoglobin determination and complete blood count are performed. These data are filled in under the heading "Donor" on a special sheet prepared for the transfusion service. This sheet is yellow, as are all records pertaining to the transfusion department. The top of the sheet concerns the history of the recipient and is filled in at the time of transfusion. It consists in data that may be interesting from the standpoint of statistics: the indication for the transfusion, the method used, the amount of blood, the type of blood and the reactions, if any. The serial number is placed on each flask, and a corresponding number on a set of records pertaining to that flask, so that at any time during the year the exact number of transfusions given may be instantly determined. It is hardly necessary to state that if, for any cause, the physical examination or history brings to light some reason why the blood should not be used for transfusion, the donor is excused.

A written permit on a special blank is secured from the donor, giving permission to administer the blood to the patient mentioned in the permit. The permit also states that if, for any reason, the blood is not compatible or is not used for the patient for whom it was secured, the hospital may employ the blood for any other purpose it may see fit. This permit is witnessed.

*Room No. 2.* The closed system for collecting blood is used. The apparatus includes an aluminum pan (Wearever, No. 2434) wrapped in a sterile covering and containing a three-holed rubber stopper, through which there is a piece

of straight glass tubing 10 cm. in length. To this is attached a piece of stiff brown-rubber tubing with a 3-mm. lumen. In the other end of this tubing is inserted a Murphy drip bulb, without the air vent, and to the other end of the Murphy drip bulb, in turn, another piece of tubing is attached. Cotton is placed in the Murphy drip bulb. The operator applies suction by water pump or by mouth to the free end of the tubing. In the second hole of the rubber stopper is placed a right-angle glass tube, and to this is attached a piece of yellow, translucent, acid-cured rubber tubing 65 cm. (26 in.) in length with a 4-mm. lumen. This tubing is directly connected with a 13-gauge or 16-gauge needle, the taking needle. A glass adapter is purposely not used because it causes both constriction in the pipe line and frequent clotting. The translucent tubing serves the same purpose as an adapter, since blood may be

FIGURE 1. Apparatus Used for Securing the Blood.

visualized through the wall of the tubing. In the third hole of the stopper, there is a short section of glass tubing the free end of which is covered with a medicine-dropper bulb. This has been arranged so that if at any time it becomes necessary to add additional citrate to the blood it may be done by inserting a syringe needle through this bulb; by this method, it is unnecessary to detach the stopper. In the aluminum pan, there is also a Fenwal metal and rubber cap, which is inserted in the neck of the bottle at the completion of the collection of the blood, thereby keeping the contents of the bottle airtight. The 500-cc. Fenwal flask in which the blood is collected has a separate sterile wrapping.

After the collecting outfit has been assembled (Fig. 1), a 50-cc. ampule of 2.5 per cent sodium citrate solution is emptied into a sterile glass con-

tainer. By suction, this fluid is drawn into the collecting flask through the needle and the rubber tubing; the flask is then agitated so that its wall is wet by the solution. This amount of sodium citrate is usually sufficient to prevent the coagulation of 450 cc. of blood. If smaller or larger amounts are to be drawn, the volume of citrate solution is varied accordingly.

The Fenwal flask, with its attachments, is placed on a stand below the level of the donor and out of his line of vision—it is important, for psychic reasons, not to allow the donor to see the amount of blood removed. During the collection, the agitation of the flask is minimized. When the desired amount of blood (usually 500 cc.) has been collected, a hemostat is applied to the translucent tubing close to the flask. This tubing is then detached from the glass tubing in the rubber stopper. Samples of blood are collected in two test tubes for serologic tests and typing by simply releasing the hemostat for the tubing. The needle is then removed from the vein. The three-way rubber stopper is removed from the flask, a sterile pipette is inserted, and a sample of the blood and preservative is withdrawn and placed in the third test tube. This test tube is known as the pilot tube, and it is from this tube that all future typing will be performed, thereby eliminating the necessity of entering the flask until it is used for transfusion or its conversion into plasma.

After the completion of the collection of blood, 25 cc. of a 50 per cent solution of dextrose and 25 cc. of distilled water are gently added to the flask containing sodium citrate and blood. When dextrose is added in this amount, the supernatant fluid usually remains perfectly clear and shows no evidence of hemolysis for as long as forty-six days. However, when this preservative is used, the flasks are routinely forwarded at the end of twenty-one days for siphonage to convert blood into plasma. Blood preserved with sodium citrate alone is converted into plasma at the end of eight days.

The refrigerator in which the blood is stored is of special design (General Electric Company, Cabinet No. 2425). With thermostatic control, the temperature is maintained at 38°F. The revolving shelves are very practical, since one thus has access to any flask on the shelf without moving or agitating the containers. The flasks of one type are grouped together on a single shelf. Flasks most recently collected are placed on the lower shelf, to be distributed later when the laboratory work is completed. The refrigerator is located in the room in which the blood collections are made.

## PROCESSING OF PLASMA

From a blood collected to process into plasma, the latter is removed twenty-four hours later, and from blood that had been intended but had not been used for transfusion, on a definite date after collection. When the bank was instituted, a combined siphon and centrifuge method was used. The centrifuge process has been eliminated because the increased yield of plasma was not sufficient to compensate the risk of contamination by an added step in technic.

A very compact and economical cabinet has been constructed to be used while the plasma is being processed. The cabinet is a workbench with a hood attached. In front of the technician is a hinged glass window to prevent breath and dust contamination. Beneath the window is a 20-cm. opening to admit sterile gloved hands. A sterile gown is worn. The top of the hood is closed to eliminate active currents of air. Attached to the upper part of the hood is a Westinghouse Sterilamp.\* The cabinet is portable and should be placed in a clean room away from traffic.

The transfer of plasma from the blood flasks to the pooling flask is carried out in a closed system. The Fenwal stopper is removed from the flask of blood. A two-holed rubber stopper is substituted. A glass tube passing through one opening is adjusted to a level just above the line of demarcation between plasma and cells. The second glass tubing acts as an air vent. A 2-liter Fenwal flask is used for pooling the plasma. This large flask is connected to the flask of blood by rubber tubing. A two-holed rubber stopper is inserted in the pooling flask, and through the second opening is a glass tube with a rubber-tube attachment for suction. Suction is produced either by water pump or by mouth. Plasma is separated from bloods of various types and collected in the pooling flask. The flask is agitated, and the process is reversed to transfer the plasma from the pooling flask to the storage bottle.

Merthiolate (Lilly) is added to each batch of pooled plasma. A 1 per cent stock solution is prepared by adding 1 gm. of Merthiolate, together with 1.4 gm. of borax as a buffer, to 100 cc. of distilled water; 1 cc. of this solution is added to every 100 cc. of plasma. A sample of each batch of

\*The Westinghouse Sterilamps are essentially monochromatic generators of ultraviolet radiation, which is highly bactericidal. The tube is set for a radiation of 28.8 microwatts per minute as measured, by a Tantalum photoelectric cell. The tube is checked monthly, and if the intensity drops, the regulator may be adjusted to maintain a constant intensity. The tube is placed 75 cm. (30 in.) above the table. The ultraviolet ray will not penetrate glass, and therefore does not affect the blood, or the eyes of the technician. In preparation for processing the plasma, a sterile drape and then the flasks and apparatus to be used are placed on the bench. The Sterilamp is lighted, and after half an hour, the technician begins her operation, working under the lighted lamp.

plasma is obtained for culture, and the latter is incubated for at least two weeks.

The plasma is stored in the refrigerator in 500-cc. straight-walled flasks sealed with Fenwal rubber and metal caps.

The pooled plasma can be used without typing and will keep indefinitely if stored in an airtight container at 38°C. without exposure to light.

### BANKING

*Credit.* Seventy per cent of cases needing transfusion can be predicted days before the actual administration of the blood. These patients are requested to have one or more donors, according to the need, report to the blood clinic at a scheduled time. The blood is collected irrespective of type, and to this patient is credited the amount donated. If for any reason the full supply of blood collected is not used, it becomes the property of the bank.

*Debit.* If, because of an emergency, a patient is required to have a transfusion, the blood for which has been furnished by the bank, this patient is in debt to the bank for the amount given and must secure donors for the next banking day. The filing system compiled by the supervisor is responsible for keeping the bank solvent.

*Banking hours.* It is the policy of the blood bank to collect on certain afternoons and evenings. This variation in time allows for different working hours of the donors and has worked out very satisfactorily. No blood is secured from donors at any other time, except in emergency.

*Cost of transfusion.* A flat charge is made for each transfusion according to the means of the

patient. This charge is comparable to any operating-room fee. Many indigent patients who are unable to secure donors for one reason or another are now transfused without expense to the hospital. The availability, the safety and the decreased cost per patient have materially increased the number of transfusions. As plasma becomes available, there will probably be an increasing trend toward its use.

### SOCIAL ASPECTS

Approximately 5 per cent of unsuspected positive serologic reactions with bloods from donors have been encountered. Afflicted donors are requested, in a carefully worded letter from the social-service department, to return to the hospital. The reason for this conference is not divulged. The social-service worker verbally informs the donor of his misfortune and arranges for his treatment.

### SUMMARY

The management of the blood bank at the Massachusetts Memorial Hospitals is outlined. Emphasis is placed on specialization in the collecting and handling of the blood and the processing of the plasma. Experience with a blood bank has shown that the cost of the personnel and equipment is not prohibitive, that the ease and frequency of transfusion are increased, and that the safety factors of transfusion are greatly improved.

## AN EVALUATION OF PERITONEOSCOPY\*

With Particular Reference to the Diagnosis of Abdominal Tumors

WALTER E. GARREY, M.D.†

BOSTON

**P**ERITONEOSCOPY, or visualization of the abdominal cavity, is far from new. However, following increased experience with an improved instrument, it is pertinent to inquire into the results that have recently been obtained. The physician wishes to know when peritoneoscopy is worth while and what information it provides that cannot be obtained in other ways. He wishes to know how much discomfort, expense and risk it involves for his patient. He wishes particularly to know how often the information obtained will materially alter the treatment.

It is not generally appreciated that this method of abdominal diagnosis is thirty-nine years old. The historical aspects have already been well reviewed by Ruddock.<sup>1</sup> In 1901, Kelling,<sup>2,3</sup> of Dresden, first demonstrated the observation of abdominal viscera on a dog, using pneumoperitoneum and a cystoscope. He later examined 2 patients by this method, one a case of ascites and the other a case of gastric carcinoma. Jacobaeus<sup>4</sup> developed an improved instrument and used the same technic. To illustrate the type of work done by these pioneers, Jacobaeus's report in 1913 of 138 such examinations included the diagnosis of 17 cases of liver cirrhosis, 31 cases of malignant abdominal tumor, 10 cases of tuberculous peritonitis, 3 cases of syphilitic liver and 9 cases of Pick's disease. Nordentöft<sup>5</sup> reported in 1912 the endoscopic examination of female pelvic organs with the patient in the Trendelenburg position. The instruments then used were too short to be certain of inspecting both the upper and the lower abdominal cavity through one insertion, had a narrow field of vision, and did not permit obtaining a biopsy.

These faults were overcome in the Ruddock<sup>1</sup> instrument, which has been in use for six years. Ruddock has reported 500 examinations with it, and is soon to report 1000 additional examinations. There is no other series nearly so large, but Benedict<sup>6,7</sup> has reported 50 and later 100 cases, and Thieme<sup>8</sup> last year published a critical survey of peritoneoscopy, based on 50 cases. The following data are based on 75 cases.

## METHOD

The detailed description of technic has been well covered by Ruddock<sup>1</sup> and is therefore only briefly outlined. A small block of the abdominal wall, preferably in the mid-line just below the umbilicus, is anesthetized by novocain infiltration. A 1.5-cm. skin incision is made. A pneumoperitoneum is induced with a small blunt trochar and cannula. A larger trochar with cannula, the latter constituting a sheath for the optical instruments, is then introduced through a nick in the anterior fascia. The instrument thus comes to lie in the space created by the insufflated air, between the abdominal wall and the abdominal viscera.

In the average case, inspection reveals the anterosuperior surface of the liver and variable amounts of the inferior liver surface near the edge. The dome of the gall-bladder fundus can almost always be viewed. The lower anterior gastric surface is seen. How much of the upper stomach is visualized depends on the degree of ptosis. The anterior surface of the great omentum and the surface of those coils of bowel not covered by it may be inspected. The pelvis can be well explored only with the patient in a very steep Trendelenburg position. In women, the uterine fundus, proximal tubes and anterior surface of the broad ligaments are readily seen. The fimbriated ends of the tubes and the ovaries may at times be prolapsed behind the broad ligaments; in these cases they are difficult to see.

The ambulatory patients in my series have averaged a thirty-six-hour stay in the hospital. In a few cases in which there was no biopsy, the patients have remained only ten hours. With increasing experience, I am convinced that there should be negligible discomfort, comparable to a well-executed abdominal paracentesis. To accomplish this, three things are necessary. First, the block of the abdominal wall, at least 5 cm. square, must be thoroughly infiltrated, with particular attention to using sufficient novocain beneath the fascia and below each rectus muscle to anesthetize the peritoneum. Secondly, the optical instrument must be gently moved, so that it does not jolt and, if possible, does not touch visceral surfaces. Thirdly, an effort must be made to press out most of the air at the end of the examination.

\*From the Joseph H. Pratt Diagnostic Hospital and the Surgical Service, Faulkner Hospital.

†Peritoneoscopic consultant, Joseph H. Pratt Diagnostic Hospital; associate staff member, Faulkner Hospital.

For satisfactory results, the facilities of an operating room are needed. An operating table that will tip steeply either way, suction and electrocautery are recommended.

I have at various times inserted the instrument into each of the four quadrants of the abdomen and the epigastrium. The cardinal rule is to keep far away from old laparotomy scars to which the hollow viscera might be adherent. The literature records a few cases of penetration of bowel due to an adherent viscus; all were detected and none were fatal. It is imperative that the pneumoperitoneum needle move freely within the abdomen to ensure that no emphysema of omentum or of abdominal wall occurs.

#### CONTRAINDICATIONS

Peritoneoscopy should never be used in the possible presence of bacterial infection in the free peritoneal cavity. Except in the diagnosis of ectopic pregnancy (Hope<sup>8</sup>), it has no place in the diagnosis of acute abdominal conditions. It has been used to see if an abdominal wall stab wound penetrated through the parietal peritoneum (Hamilton<sup>10</sup>). This seems safe only in an early case, and then only with preparations to follow at once with a laparotomy if penetration through all the layers of the abdominal wall has occurred. The pneumoperitoneum may produce some reduction of vital capacity. If there is an appreciable amount of hydrothorax, the fluid should be removed before peritoneoscopy. Naturally, decompensated heart disease is a contraindication. Age and senility alone are no contraindication. 14 of the patients in this series were over the age of sixty, and 2 were over the age of eighty.

#### COMPLICATIONS

In the 75 cases, there has been no mortality attributable to peritoneoscopy. There has been no complication since the second case, in which sepsis occurred in the abdominal wall as the result of contamination from the wound of a previous piracentesis. Complications listed in the literature are emphysema of the abdominal wall,<sup>6</sup> hematoma in the wound of entrance<sup>8</sup> and bleeding from the site of biopsy.<sup>1</sup> Hematoma in the abdominal wound in cases with liver damage may be prevented in the future by use of vitamin K. Electrocoagulation of biopsy sites must be carefully performed if any appreciable bleeding occurs.

#### FIELD OF USEFULNESS

There are four broad groups of conditions in which peritoneoscopy may confirm a diagnosis, render an exploratory laparotomy unnecessary, and

aid materially in giving a prognosis, namely, to determine the presence, extent, nature and operability of cancer, to demonstrate the nature and extent of pelvic tumors and of lesions of the female pelvic organs, to make the differential diagnosis of ascites, and to make the differential diagnosis of liver disease. Naturally these groups overlap. In this series, the following diagnoses were correctly made:

DIAGNOSIS	NO OF CASES
<b>Malignancy</b>	
Metastatic carcinoma in the liver	11
Peritoneal carcinomatosis	6
Gastric carcinoma, without metastases	5
Metastatic fibrosarcoma of the peritoneum	1
Melanotic sarcoma in the liver	1
Primary hepatoma of the liver	1
<b>Tumors of the female pelvic organs</b>	
Ovarian carcinoma	7
Malignant ovarian cyst	1
Benign ovarian cyst, with twisted pedicle	1
Benign ovarian cyst	1
Fibroid uterus	1
<b>Differential diagnosis of ascites and liver disease</b>	
Cirrhosis of the liver	14
Syphilis of the liver	1
Splenomegaly, without cirrhosis	1
Fatty infiltration of the liver	1
Inflammatory mass below the liver	1
Carcinoma of head of the pancreas (presumptive)	1
Tuberculous peritonitis	1
Multiple adhesions	1

In the remaining 18 cases, peritoneoscopy showed the visualized portion of the abdominal cavity to be normal. These patients had hypernephroma, calcified mesenteric masses, retroperitoneal tumors, vaginal carcinoma, rectal carcinoma and so forth. Two obese patients, thought probably to have abdominal tumors, were shown to have none.

Early leaking of blood from an ectopic pregnancy is diagnosable with great accuracy.<sup>9</sup> The peritoneoscope has been used to sterilize the female by electrocoagulation of the isthmal portion of the Fallopian tubes under direct vision (Anderson<sup>11</sup>). This attempt at operative peritoneoscopy has even been carried farther in suturing the internal orifices of inguinal hernia under direct vision (Ruddock, quoted by Sawyer<sup>12</sup>). It seems that these operative procedures are more surely and safely performed by laparotomy. However, I have had no personal experience on which to base such a conclusion.

#### ACCURACY OF DIAGNOSIS

There is no case in which I am, as yet, aware of an erroneous diagnosis; biopsies were obtained

in 15 cases. In 2 cases, however, a conclusive diagnosis could not be made. One patient was a man with ascites who previously had had extensive gastric surgery for peptic ulcer. Because of numerous adhesions, only a small portion of the right upper peritoneal cavity and liver surface was available for inspection. In the second case, a carcinoma of the gall-bladder area was suspected, but the omentum had become densely adherent to both gall bladder and liver, and hence a satisfactory view could not be obtained. In the second case, exploratory laparotomy was advised and performed, and a carcinoma of the gall bladder, with metastasis, was found.

Thieme<sup>8</sup> has pointed out that the largest groups of cases for peritoneoscopy are those in which the diagnosis is already strongly suspected and only absolute confirmation is wanting. There is another small group of cases in which every diagnostic procedure short of exploratory laparotomy has failed to give the diagnosis. In these cases, the result of peritoneoscopy may be quite dramatic. Case 1 is illustrative.

CASE 1. Mrs. B. B. (J. H. P. D. H. 5350), a 46-year-old housewife, entered the hospital complaining of weakness and fullness in the pit of the stomach for over a year. One year previously, she had had frequent and profuse menstrual periods and had been examined at a clinic, where fibroids were found. Five months before entry, she became troubled by indigestion, and the vaginal bleeding ceased. Four weeks prior to entry, she had lancinating pain in the right upper quadrant lasting for several hours. There had been definitely increasing dyspnea on exertion. Physical examination showed a palpable liver, a fibroid uterus, a slight anemia and a slight and irregular fever. X-ray examination of the gall bladder, stomach and colon was negative. On entry, x-ray films of the chest were negative, but later showed fluid in the right chest.

Peritoneoscopy confirmed the diagnosis of a fibroid uterus. The stomach, omentum and peritoneal wall were normal, but on the superior surface of the liver two yellow nodules, several centimeters in diameter, were seen that had the appearance of metastatic carcinoma. A biopsy report indicated carcinomatous metastasis to the liver; the primary source was not known. This patient gradually failed and died.

In this patient, x-ray examination and all other diagnostic studies failed to give the diagnosis, yet metastatic carcinoma was present. Two other cases were identical.

In 2 cases, intra-abdominal cancer was strongly suspected, but peritoneoscopy fortunately proved the presence of benign lesions. One was a case of syphilitic liver, and the other an intraomental abscess of unknown etiology; an abstract of the latter follows.

CASE 2. J. G. (J. H. P. D. H. 327-395), a 40-year-old Lithuanian, entered the hospital complaining of steady pain in the right upper abdomen of 10 days' duration. No

jaundice, nausea or other symptoms were noted. Seven and a half years previously, however, he had an attack of right upper abdominal pain followed by jaundice. This was thought to be due to acute hepatitis. On examination, he had a rounded, exquisitely tender, right-upper-quadrant mass and ran a slightly elevated temperature (average 100.5°F.). He had a moderate anemia (hemoglobin 63 per cent), and white-cell counts ranged from 7000 to 10,000. He was thought possibly to have either a hydrops of the gall bladder or a cancer. However, an entirely normal cholecystogram was obtained.

In this case, the peritoneoscope was introduced in the left upper quadrant. The inferior surface of the liver was entirely normal. Numerous inflammatory adhesions in the right upper abdomen formed a curtain between the abdominal wall and the inner edge of the liver, and a large mass of omentum was densely adherent to the abdominal wall. Pericholecystic abscess seemed the likeliest diagnosis, yet could hardly have been present, since the Graham test was normal. An operation was performed, and a necrotic inflammatory mass was found in the omentum. Its origin was undetermined but thought possibly to be the result of a pancreatitis.

Here again, short of exploratory laparotomy, no diagnosis was possible other than by the means of peritoneoscopy. However, in this case a laparotomy was eventually needed.

#### GENERAL CONSIDERATIONS

##### *Carcinoma of the Stomach*

Some writers believe that every case of carcinoma of the stomach should be examined by peritoneoscopy before operation to determine the presence or absence of peritoneal and liver metastasis. If a palliative operation is indicated in any case, I consider peritoneoscopy unnecessary. Moreover, the operability in relation to posterior fixation and retroperitoneal metastases cannot be determined by peritoneoscopy. However, it is true that a small growth may already have hepatic metastases, whereas a large growth may have none and yet be quite operable. Peritoneoscopy may give strong evidence for either of these situations.

CASE 3. A. N. (F. H. 57649), a 62-year-old man, entered the hospital complaining of weakness, epigastric distress and evening anorexia of 2 weeks' duration. There was no nausea or vomiting, and a loss of only 6 pounds in weight. X-ray study showed a small carcinoma in the antrum of the stomach. Peritoneoscopy disclosed some confluent yellow masses in the left lobe of the liver typical of metastatic tumor, and a biopsy was obtained. No operation was performed, and the patient died 4 months later.

This man had a small carcinoma, with a short duration of symptoms, yet peritoneoscopy disclosed liver metastases. He later died without developing symptoms that surgery could have alleviated.

CASE 4. L. S. (F. H. 56330), a 63-year-old carpenter, complained of weakness, weight loss and tarry stools of 10 months' duration. The patient was emaciated. A large mass was palpable in the epigastrium. X-ray examina-

tion showed a large filling defect of the antrum of the stomach. Peritoneoscopy readily visualized the liver, and no metastases were present. No metastases were seen on the peritoneum, and the tumor did not appear to have come through the gastric surface. The patient was operated on, and an extensive resection performed after which he did well.

In contrast to the patient in Case 3, this man had a large growth of considerable duration. Symptoms were compatible with the presence of metastases. Peritoneoscopy gave encouragement to preparation for an extensive resection, which was carried out successfully.

### *Tumors of the Female Pelvic Organs*

In the majority of women, peritoneoscopies have been performed for the purpose of confirming by biopsy a strongly suspected diagnosis of ovarian

since no pelvic tumor could be felt. The diagnosis of a radiosensitive pelvic neoplasm was established.

**CASE 6** Mrs J R (F H 57461), a 43-year-old housewife had complained for 3 months, of an intermittent dull pain in the left flank. The catamenia were normal, and no genitourinary or gastrointestinal symptoms were noted. Examination showed an enormously obese woman with an overhanging panniculus of abdominal fat. An indefinite mass was at times felt high in the left pelvis. Abdominal x-ray examination was negative.

Peritoneoscopy showed a 10-cm ovarian cyst with a partial clockwise twist in its pedicle, but with no impairment of its blood supply. The other pelvic organs were normal.

The presence of an abdominal tumor was confirmed, and its nature determined, in an extremely obese woman in whom the very existence of the tumor was in some doubt.

### *Jaundice and Liver Diseases*

Peritoneoscopy is of greatest help in patients with jaundice and liver disease. A direct visualization of the liver and, if necessary, a biopsy give a far more accurate diagnosis than one based on clinical history and tests of liver function. The picture of cirrhosis, in contrast to the normal smooth liver surface, is as clear through the peritoneoscope as it is in the post mortem room. In cases of icterus without jaundice, and cases of intermittent jaundice with or without pain, the peritoneoscope will rule cirrhosis in or out. If a laparotomy must follow, to examine the pancreas or bile ducts, it will be performed with the conviction of its urgent need.

**CASE 7** R M (J H P D H 5143), a 59-year-old plumber, had felt weak and had tired easily for 14 months. Twelve months before entry slight jaundice had appeared and he consulted a clinic. All studies including a gastrointestinal series were negative. The degree of jaundice varied during the ensuing year; at times there was none. A medical consultant believed that statistically there was a 70 per cent chance that the trouble was due entirely to cirrhosis.

Peritoneoscopy showed an absolutely smooth liver surface and a greatly enlarged gall bladder fundus. This was considered strongly suggestive of an obstructing lesion of the lower biliary ducts.

A subsequent barium meal showed some narrowing of the second portion of the duodenum. At operation a carcinoma of the head of the pancreas was found.

### *SUMMARY AND CONCLUSIONS*

Peritoneoscopy has been safely performed in 75 cases. The gross pathologic lesions were identical

FIGURE 1 Ovarian Cyst and Female Pelvis as Seen through the Peritoneoscope (Case 6)

carcinoma. Some of the patients had ascites, and in 2 cases the pelvic tumors were not palpable from below, the peritoneoscope was consequently the only method of making a diagnosis and enabling x-ray treatment to be started.

**CASE 5** Mrs M D (F H 13161), a 49-year-old housewife entered the hospital complaining of a swollen abdomen of 7 months' duration. Examination showed some evidence of weight loss. No pelvic masses were felt. Repeated abdominal taps failed to give a diagnosis on spun sediment. Peritoneoscopy showed a nodular mass typical of ovarian tumor involving the left broad ligament and a biopsy showed a papillary adenocarcinoma.

Cirrhosis of the liver was considered in this case,

fied and a correct diagnosis returned in 55 cases. In 2 cases, both complicated by adhesions, it was impossible to be certain of the diagnosis. Fifteen biopsies were performed, all of which showed either a malignant tumor or a diseased liver. In

## MYOMECTOMY DURING PREGNANCY\*

ROX J HEFFERNAN, MD†

BROOKLINE, MASSACHUSETTS

**A**LTHOUGH fibroids frequently coexist with pregnancy, they rarely cause serious complications. Pierson<sup>1</sup> found only 191 cases, or 0.6 per cent, of clinically important fibromyoma in 30,836 consecutive pregnancies analyzed at the Sloane Hospital for Women.

The uterus is usually very tolerant of the presence of fibroids, and I have observed many women with large tumors who progressed without difficulty through pregnancy, labor and the puerperium. The large growths are more frequently seen in elderly primiparas or in multiparas whose last baby was born several years previously. Fibroids that are palpated low on the uterine wall early in pregnancy may, as the uterus enlarges, be retracted out of the pelvis so that they offer no obstruction to labor. Intraligamentary and cervical fibroids usually do remain pelvic, however, and may necessitate abdominal delivery.

The occurrence of spontaneous abortion and premature labor is high. Pierson found it in 24.1 per cent of his series. Torsion of the pedicle may occur. A fibroid in the posterior wall may prevent replacement of a retroverted or retroflexed uterus. In 1930, I reported the suspension of an incarcerated, two-months-pregnant uterus with a large fibroid on the posterior wall. All attempts at replacement by conservative methods had failed, and miscarriage seemed imminent. The patient was delivered at term, and a myomectomy was performed four months later.

The chief complication during the prenatal period, however, is degeneration, the commonest type of which is so-called "red degeneration." This may occur with or without secondary hemorrhage in the tumor and is always associated with pain. The morbid process does not as a rule progress to actual death of the cells, but in neglected cases liquefaction and necrosis may ensue. Following this, the aseptic devitalized tissue may become infected through the blood stream or by contiguity from adherent intestine. The exact cause of this degeneration is not known, but it is believed to result from an interference with the blood supply of the fibroid by changes occurring in the pregnant uterus. This would explain why degeneration of these tumors is commoner dur-

ing the puerperium. The post partum administration of ergot should be withheld in these patients unless subinvolution or excessive flowing makes its use imperative.

Clinically, the onset of degenerative changes in the tumor is marked by pain, usually severe, over the site of the growth. An elevation of temperature of one or two degrees is usually noted, accompanied by moderate leukocytosis. Vaginal bleeding may or may not occur. In mild cases, the symptoms subside under rest and sedatives to control the pain. Conservative treatment should be given a thorough trial, but if the pain increases and the temperature and leukocyte count indicate that the degeneration is progressing unfavorably, surgery should be considered.

A report of 4 cases in which the fibroid was enucleated during pregnancy is presented.

## CASE REPORTS

**CASE 1.** Mrs. T., a 38 year-old woman, had been married 9 years and had never been pregnant. Her last regular period began on May 12, 1930. She flowed moderately from July 7 to 9 and then stained for 3 weeks. There was no pain or cramps, and she did not pass clots.

The patient had had no serious illnesses since childhood but a herniotomy and hemorrhoidectomy had been performed 12 years previously.

On September 3, she developed severe pain in the left lower quadrant and began to flow moderately. On examination, the abdomen was relaxed, and a tender mass could be felt in the left lower quadrant. Vaginal examination revealed a primiparous introitus, with a slight bloody discharge. The fundus was in good anterior position and was enlarged to a size consistent with a 3 months pregnancy. A firm, very tender mass, apparently attached to the uterus, could be felt in the left vault.

The temperature was 99.8°F, the pulse 96 and the respirations 22. The white-cell count was 12,500. The patient was admitted to the Trumbull Hospital. The following day, the pain had increased in severity, the temperature was 100°F, the pulse 98. The vaginal flowing persisted. On September 8 the white-cell count had risen to 16,000. The flowing increased, and two large clots were passed. The pain in the left lower quadrant became severe and could not be entirely controlled by sedatives. Laparotomy on that date revealed a uterus the size of a 3 months pregnancy, with a mottled, congested, apple-sized fibroid on the left anterior wall. Myomectomy was performed. Pathological examination of the tumor revealed red degeneration with marked small round-cell and polymorphonuclear infiltration. The following day, the patient was free from pain, and on the 3rd postoperative day the vaginal bleeding stopped and did not recur. Recovery was uneventful and pregnancy progressed normally until March 14, 1931. On that date, the membranes ruptured at 3 a.m. and the patient

\*Read at a meeting of the New England Obstetrical and Gynecological Society at the Carney Hospital, Boston, December 4, 1940.

†Instructor in gynecology, Tufts College Medical School; visiting gynecologist and obstetrician, Carney Hospital.

was admitted to the Massachusetts Women's Hospital. After 8 hours of ineffectual labor, a diagnosis of cephalopelvic disproportion was made, and a transverse cervical cesarean section was performed. On inspection, the myomectomy scar was found to be firm. A normal 10-pound, 4-ounce, baby was delivered, and after a normal convalescence the patient left the hospital on the 14th day.

CASE 2. Mrs. M., a 34-year-old woman, was seen in consultation at St. Margaret's Hospital on July 3, 1930. She had had two full-term normal deliveries, the last 5 years previously. Both children were living and well, and there had been no miscarriages. There had been no serious illness and no operations. The last regular period began on April 10, but there had been some irregular flowing off and on since that date and the patient did not believe that she was pregnant. On July 2, a laparotomy had been performed, and the uterus was found to be enlarged to a size consistent with a 2½ months' pregnancy. It was soft and blue, with a fibroid the size of a baseball growing from the fundus. A myomectomy was performed. When I saw the patient the following day, there was a slight bloody vaginal discharge, which ceased after 3 days. On July 12, vaginal examination revealed a uterus the size of a 3 months' pregnancy, with the fundus in good anterior position.

No further flowing occurred, and pregnancy proceeded normally to January 14, 1931. On that date, the patient was awakened at 5 a.m. by labor pains recurring every 5 minutes. She was admitted to St. Margaret's Hospital at 5:46 a.m. and delivered precipitately 6 minutes later. The normal infant weighed 7 pounds, 8 ounces, and the mother made an uneventful recovery.

CASE 3. Mrs. M., a 35-year-old woman, had been married 6 years. She had had no children or miscarriages. Her chief complaint was severe pain in the right lower quadrant of 2 days' duration. The last regular period began on June 27, 1931. On October 2, there had been a slight show of blood, with slight pain in the right lower quadrant. Two days later, the flowing increased, the pain became severer, and the patient was admitted to the Carney Hospital.

An attack of rheumatic fever, which did not affect the heart, was experienced in 1922. This was followed by a tonsillectomy, and there had been no recurrence. A hemorrhoidectomy had been performed 1 year previously.

On examination, there was marked tenderness in the right lower quadrant, and an indefinite mass could be felt, apparently attached to the uterus. There was no muscular spasm. On vaginal examination, the fundus was found to be enlarged to the size of a 3 months' pregnancy and was in good anterior position. There was a slight, steady, bloody vaginal discharge. On admission the temperature was 100.2°F., the pulse 94, the respirations 20, and the leukocyte count 12,000. The following day the flow increased, the temperature rose to 101.4°F., and the pain became severer.

On October 6, there was a steady bright-red vaginal flow, and the mass in the right lower quadrant was exquisitely tender. The white-cell count had risen to 15,600. Laparotomy revealed a uterus the size of a 3½ months' pregnancy, with a mottled, egg-sized fibroid protruding from the right anterior wall. A fibroid about half that size was seen on the left anterior surface of the uterus near the bladder reflection. The larger fibroid was enucleated. It extended well into the wall of the uterus, and a small area of amniotic sac could be seen

glistening in the depths of the uterine wound after the tumor had been removed. A few deep sutures were carefully placed, and the uterine incision closed. The smaller tumor was enucleated without difficulty. The patient made an uneventful recovery, and there was no vaginal bleeding after the 4th postoperative day.

Pregnancy progressed normally to term. On April 21, 1932, the patient was 2 weeks overdue. Because of cephalopelvic disproportion, on April 22, the patient was delivered by transverse cesarean section. The baby weighed 9 pounds, 6 ounces. The myomectomy scars were inspected and found to be firm. The patient made an uneventful recovery and was discharged 2 weeks later.

CASE 4. Mrs. C., a 39-year-old primipara, was seen in consultation with Dr. Chester Goodnow, of Franklin, Massachusetts, on October 31, 1939. Her last period began on March 21, and the expected date of confinement was December 28. For the previous month, the patient had had increasing discomfort and pain in the right flank. For 2 weeks, the pain had been so severe that the patient was unable to sleep. There had been no nausea or vomiting, and no flowing of blood since the last period.

The patient had always been well since childhood, and there had been no operations.

On examination, the fundus was found to be 4 finger-breadths below the ensiform; the fetal heart was heard in the left lower quadrant, and the rate was 144. A tender mass the size of an orange, apparently attached to the uterus but freely movable, could be felt about 8 cm. above the anterosuperior spine of the ilium. The tumor was exquisitely tender. The temperature, pulse and respirations were normal. The blood pressure was 136/84, and urinalysis was negative. On vaginal examination, the cervix could be palpated high in the vagina, and there were no pelvic masses or tenderness. The patient was anxious to have a normal, full-term baby, but said that she could not stand the pain any longer and requested that something be done.

The patient was admitted to the Milford Hospital on November 2. On the following day, laparotomy revealed a mottled, congested, pedunculated fibroid. A myomectomy was performed. An ampule of Progestin was administered daily for 4 days, and then twice a week for the next 2 weeks. Capsules of wheat-germ oil were also prescribed for a period of 4 weeks.

Pregnancy progressed without further incident, and the patient entered the Milford Hospital in labor on December 30. A normal, 7-pound, 4-ounce baby was delivered by low forceps by Dr. Goodnow. The post-partum period was uneventful, and the patient was discharged on the 13th day.

#### SUMMARY AND CONCLUSIONS

Fibroid tumors of the uterus usually have no harmful effect on a coexisting pregnancy.

The patient should be kept under careful observation for complications such as miscarriage or premature labor, obstruction to the descent of the presenting part and degeneration of the fibroid.

So-called "red degeneration" of the tumor is the type usually found, and it occurs most frequently during the puerperium, probably because involution disturbs its blood supply. Degeneration may also occur during the prenatal period. Its onset is

always marked by pain, occasionally accompanied by fever and leukocytosis.

When the degeneration is slight, the symptoms may be relieved by medical treatment, but in the severer types the tumor should be removed. Interruption of the pregnancy should not result from the operation. On the contrary, myomectomy seems to prevent miscarriage.

Corpus luteum hormone and wheat-germ oil

should be administered prophylactically, whether the fibroid is treated conservatively or removed.

Four cases of myomectomy during pregnancy, with delivery at term, are presented.

## MEDICAL PROGRESS

### CHEMOTHERAPY OF PNEUMONIA\*

With Special Reference to the Present Status of Sulfadiazine

MAXWELL FINLAND, M.D.†

BOSTON

ANY review of recent progress in the treatment of pneumonia must concern itself primarily with chemotherapy. New developments continue to take place rapidly in this field. Lord's<sup>1</sup> summary in 1939 covered the introduction of sulfonamide drugs in the treatment of pneumococcal pneumonias. He concluded that sulfanilamide, the first important chemical of the group to be widely used in this country, although it had some value in the treatment of pneumonia was less effective and likelier to produce toxic effects than sulfapyridine. The latter had already received quite extensive clinical trial at that time, and the favorable results of its use were fully corroborated in many further reports<sup>2</sup> collected from the literature during the following year.

#### RESULTS OF SULFATHIAZOLE THERAPY

Sulfathiazole made its appearance shortly before the last review.<sup>2</sup> The preliminary clinical observations at that time indicated that this drug was less toxic than sulfapyridine, particularly with respect to nausea and vomiting, which were the most frequent and very disturbing features of sulfapyridine therapy. The two drugs appeared to be about equally effective in the treatment of the pneumococcal pneumonias.

#### Mortality

Numerous reports dealing with sulfathiazole therapy have appeared during the past year. The pneumonias in adults treated with this drug by a

number of different authors<sup>3-10</sup> include 1045 cases of pneumococcal pneumonia, with 98 deaths, a mortality of 9.4 per cent. These cases also include patients (about 9 per cent of the total) who received serum in addition to sulfathiazole, usually because of inadequate response to the drug. Also included are cases treated with sulfamethylthiazole, which was found to have a very similar action but which, owing to the development of occasional cases of peripheral-nerve lesions and even encephalopathy<sup>16, 17</sup> resulting from its use, was subsequently withdrawn from further clinical trial. A few authors<sup>7-9</sup> have also included comparable and contemporaneous cases from the same clinics treated with sulfapyridine, alone or with serum, both used in about the same manner as in the sulfathiazole-treated cases. There were 1501 such sulfapyridine-treated cases, with 204 deaths, a mortality of 13.7 per cent. Bacteremia was just as frequent in either group, — 15.2 and 15.3 per cent in the patients treated with sulfathiazole and sulfapyridine, respectively, — but the mortality in these bacteremic cases was 25.2 per cent among the former as compared with 32.6 per cent in the latter.

In general, individual reports have indicated that the effect on mortality and on the clinical course in adults was about the same or slightly better with sulfathiazole as compared with sulfapyridine. Some writers<sup>6, 8</sup> have noted a more rapid defervescence in sulfapyridine-treated cases, but this may have been due, at least in part, to the antipyretic effect of this drug, which either is lacking or is less apparent with sulfathiazole.<sup>18</sup>

#### Results in Children

In the pneumonias of infants and children, also, the effects of these two drugs have been very similar.<sup>19-21</sup> In the largest series,<sup>22</sup> the mortality

\*All articles in this series will be published in book form: the current volume is *Medical Progress Annual 1940* (Springfield, Illinois: Charles C. Thomas Company, 1941, \$4.00).

†From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital and the Department of Medicine, Harvard Medical School.

Assistant professor of medicine, Harvard Medical School; chief, Fourth Medical Service, Boston City Hospital; assistant physician, Thorndike Memorial Laboratory.

was 4 per cent in patients under the age of two years and 2 per cent in those over two years. Patients who were moribund on admission and died within twenty-four hours of entry to the hospital were also included. The latter cases accounted for about half the fatalities. The average duration of fever was almost exactly the same with the two drugs.

### *Toxicity*

Sulfathiazole has proved simpler to administer than sulfapyridine, solely because it produces nausea and vomiting less frequently. Among adults, this effect is observed in 20 to 40 per cent of sulfathiazole recipients, as compared with 60 per cent or more of those who receive sulfapyridine. It is noted much less frequently in infants and children treated with either drug. Furthermore, the severity of this symptom is considerably less when sulfathiazole is used, so that therapy must be discontinued or interrupted less frequently. This may be the explanation for the lower incidence of relapses of fever and of pulmonary signs and symptoms after sulfathiazole therapy is discontinued, as compared with the incidence of these complications with sulfapyridine treatment. It may also account for the larger average amounts of drug used in the sulfathiazole-treated pneumonias. The larger dosage, however, may also be explained, in part, by the lower blood levels obtained when sulfathiazole is used in the same doses as sulfapyridine. Some physicians are consequently inclined to increase the dose of sulfathiazole in an attempt to obtain higher levels.

Sulfathiazole also has the advantage of not producing cyanosis or anemia, and it produces serious leukopenia and liver damage less often than sulfapyridine. On the other hand, drug fevers and rashes occur much more frequently with sulfathiazole. The characteristic lesions, which resemble erythema nodosum, on the extensor surfaces of the extremities, in addition to the episcleritis and the erysipeloid lesions of the face and the severe arthritis that sometimes accompanies the skin manifestations, are features of sulfathiazole toxicity not met with in sulfapyridine-treated cases.

### *Renal Symptoms*

The most important toxic effects of sulfathiazole therapy, however, are the renal complications, which are encountered at least as frequently and probably oftener than with sulfapyridine and may be considerably more serious.<sup>22-30</sup> The increased danger from the renal complications of sulfathiazole therapy is related to the tendency

of this chemical to precipitate, in both the free and the acetylated form, in the tubules of the kidneys, and thus to interfere with renal function either mechanically or by a direct action on the tubular epithelium. This mechanism may be operative in sulfapyridine-treated cases,<sup>31</sup> but is not the usual mechanism with that drug. It may account for some failures to obtain relief of sulfathiazole anuria by catheterization of the ureters and lavage of the kidney pelvis and of the ureters, a method that is often successful if applied early in the anuria caused by sulfapyridine.<sup>32-36</sup> With sulfapyridine, the concretions of the acetylated drug are usually limited to the kidney pelvis, the ureters and the bladder. Reduced renal function in the course of continuous sulfathiazole therapy is not infrequent in animals and in clinical cases, but the function usually returns to normal after the drug is discontinued.

Because of the frequency and possible severity of the renal complications, it is essential to be on the alert for the earliest evidence of kidney damage in every patient who is treated with sulfathiazole. The urinary output must be maintained at about 1500 cc. or more daily (in adults), and the fluid intake should be adjusted accordingly. Usually, an intake of about 3000 cc. a day is necessary. Diminution in urinary output, the appearance of hematuria, retention of the drug in the blood or elevation of the blood nonprotein nitrogen is a danger sign. When one of these manifestations occurs, the drug must be stopped or the dose reduced, and the fluid intake increased. Intravenous or subcutaneous fluid in the form of physiologic saline or of 0.5 per cent glucose in water may well be used at first. Alkalies may also be helpful, and may be given as bicarbonate of soda by mouth or as a one-sixth molar solution of sodium lactate intravenously.

### TREND IN PNEUMONIA MORTALITY

Mention was made last year of the trend in mortality since the introduction of effective sulfonamides.<sup>2, 37</sup> The gross mortality for the country as a whole is difficult to evaluate because of many factors involved in the collection of such data. Some of the clinical reports, however, seem to indicate a rising case-fatality rate in chemically treated cases, even when the same drug is employed. Thus the mortality among adults in Lord's<sup>1</sup> collected cases treated with sulfapyridine was 6.3 per cent. Among the cases collected during the following year, the mortality was 9.8 per cent,<sup>2</sup> and, as noted above, the mortality was 13.7 per cent in sulfapyridine-treated cases reported during the past year by a number of workers. To

be sure, the data for the successive years are not strictly comparable, but a similar rise in the case-fatality rate has been noted in more selected groups, as, for example, in the pneumococcal pneumonias reported by a group of workers in Philadelphia. In their earliest experience with sulfapyridine, they<sup>38</sup> reported a mortality of 70 per cent in 400 cases. During the following year, they recorded a mortality of 150 per cent in 200 cases treated with the same drug. In that year, they had a mortality of 110 per cent in a parallel series of 200 cases treated with sulfathiazole. Early last season, the same group<sup>14</sup> reported two parallel series, each consisting of 100 cases of pneumonia, one series treated with sulfathiazole, with 17 deaths, and the other treated with sulfadiazine, with 11 deaths. If only the "typed" pneumococcal pneumonias are considered, as in their previous studies, the mortality in the sulfathiazole treated cases was 19 per cent and in the sulfadiazine cases it was 13 per cent.<sup>13</sup>

A number of possible explanations of this trend may be mentioned. The first is that the severity of the disease has increased. The slight increase in the incidence of bacteremia, with the rising mortality, lends some support to this view. An increase in the occurrence of "drug resistant" strains might account for more failures of drug therapy, but this has been proved only in rare cases. It is possible that, as the early enthusiasm accompanying a new clinical therapeutic venture wore off, stricter criteria were used in the choice of cases for inclusion in succeeding studies. This explanation likewise seems inadequate, since, if anything, the general trend has been in the opposite direction and more cases are being included for chemotherapy as experience with the drugs increases. It seems likelier that in most communities, as acquaintance with the sulfonamides diffuses among physicians, greater numbers of cases are treated by them in the home. Only the severer cases and those offering difficulties in management are sent to the clinics from which the reports emanate. Thus, in a large municipal hospital receiving primarily indigent patients, few of whom could afford treatment by private physicians, the mortality in all specifically treated cases has actually dropped in the last three successive years.<sup>7, 39, 40</sup>

That chemotherapy may be used successfully in the home in the great majority of cases, even among indigent patients, is shown strikingly by the work of the group of physicians at the Boston Dispensary, who are interested in domiciliary medicine.<sup>41</sup> Because most cases are successfully treated in the home, it is to be expected that hos-

pital clinics and physicians engaged exclusively in consultation practice will have a higher mortality in their pneumonia cases than the internist or general practitioner in private practice.<sup>42</sup>

#### SULFADIAZINE

Of the more recent sulfonamide compounds, the one that has received the most extensive trials during the past season is sulfadiazine. This chemical, which was prepared by Roblin and his associates,<sup>43</sup> is the pyrimidine (diazine) analog of sulfapyridine and sulfathiazole. A preliminary report concerning this drug was made by Long<sup>44</sup> for the Council on Pharmacy and Chemistry of the American Medical Association, and the laboratory and clinical results obtained at the Boston City Hospital have also been published recently.<sup>10</sup> Although these two papers summarize most of the relevant data about sulfadiazine that are available at the time of this writing, the drug has proved to be of sufficient interest in relation to the treatment of pneumonia and other infections to warrant the inclusion here of a review of the more important information available concerning its use.

#### *Results in Animals*

Pharmacologic and therapeutic experiments with sulfadiazine were carried out in animals by Feinstein and his associates.<sup>45</sup> They found that this compound is less toxic than either sulfapyridine or sulfathiazole in acute experiments in mice, and that it produces less tissue damage than the latter drugs after prolonged administration in monkeys. They showed that sulfadiazine is absorbed fairly rapidly after oral administration, and that much higher levels are reached in the blood and are maintained longer than when the same doses of the other sulfonamides are used. Furthermore, the drug is found in the blood primarily in the free or unconjugated form. The acetyl derivative of sulfadiazine is excreted rapidly in the urine, where it is more soluble than the corresponding forms of sulfapyridine or sulfathiazole. Using identical dosage in mice, Feinstein found sulfadiazine to be more effective than either sulfapyridine or sulfathiazole against infections with hemolytic streptococcus, Type 1 pneumococcus and Type B Friedlander's bacillus, and about as effective as sulfathiazole against infections with staphylococcus.

Long<sup>44</sup> showed that in mice kept at the same blood levels, which can be maintained with considerably smaller doses of sulfadiazine than of the other sulfonamides, this drug is somewhat less effective than sulfanilamide against hemolytic

streptococcus and also slightly less effective than sulfapyridine or sulfathiazole in Type-1 pneumococcus infections, but is equal if not superior to sulfathiazole against staphylococcal infections. He also noted that sulfadiazine, when administered orally or locally, is more effective than sulfapyridine or sulfathiazole in experimental infections produced in mice by the intramuscular injection of *Clostridium welchii* and *Cl. oedematis maligni*, but that none of the drugs have any effect against *Cl. oedematis* infections. Klinefelter<sup>16</sup> found that sulfadiazine is also more effective than sulfathiazole against *Escherichia coli* infections in mice. He maintained approximately the same blood levels with about one tenth as much sulfadiazine.

### Results in Vitro

Studies on the effect of sulfadiazine on the growth of various bacteria in vitro<sup>40, 46-50</sup> have been inconsistent and somewhat misleading, since they have not always paralleled the effects observed in clinical and experimental infections. Against most of the organisms tested, it has been found to be about as effective as sulfathiazole, but against others it appears to be much less effective. The discrepancies may be accounted for by the methods used. In particular, they may be associated with differences in the mediums used for the tests, some of which may exert a selectively greater inhibiting effect on some drugs than on others. This has been shown to be true in test-tube experiments with pneumococcus.<sup>17</sup>

### Absorption and Excretion in Man

The absorption, excretion and distribution of sulfadiazine in human subjects with normal renal function have been studied by several workers.<sup>44, 51-54</sup> As in animals, higher concentrations are reached in the blood and are maintained for longer periods than with the same dose of any of the other commonly used sulfonamides, namely, sulfanilamide, sulfapyridine and sulfathiazole. Absorption from oral administration may be somewhat slower than with the latter compounds. Very little of the acetylated derivative is found in the blood. Up to 80 per cent of the ingested drug is excreted into the urine, and about one third of the drug recovered from this source is in the conjugated (acetylated) form. The drug diffuses rather slowly into the cerebrospinal fluid, requiring about eight to twelve hours to reach an equilibrium with the blood. On continuous therapy, the concentration in spinal fluid is usually about 80 per cent of the blood level, but may range from 50 to over 90 per cent. In pleural and ascitic fluids, the levels are essentially the same as in the

blood. Sulfadiazine, like sulfapyridine and sulfathiazole, is only very slightly absorbed after rectal administration, even when the sodium salt is used. Like sulfathiazole, and in contrast to sulfapyridine and sulfanilamide, sulfadiazine is found in much lower concentration in the red blood cells than in the surrounding plasma.

### Parenteral Administration

The sodium salt of sulfadiazine has been used parenterally in the same manner as the corresponding salt of sulfapyridine and sulfathiazole. It has been given intravenously as a 5 per cent solution in distilled water, or in concentrations of 0.5 to 2.0 per cent in physiologic saline solution, and has also been injected subcutaneously and intrathecally in 0.5 per cent solution in physiologic saline solution, without untoward effects.

### Clinical Results in Pneumonia and Other Infections

Published clinical data are still comparatively meager and, for the most part, are given only in preliminary form. In the two parallel series of 100 pneumonia cases referred to previously, the effectiveness of sulfadiazine compared favorably with that of sulfathiazole, with respect both to mortality and to the rapidity with which the temperature fell in the recovered cases.<sup>8</sup> Long,<sup>44</sup> in his early experience, found that "sulfadiazine is slightly less effective than sulfapyridine or sulfathiazole in the treatment of pneumococcal pneumonia in human beings and that it is of definite value in the treatment of hemolytic streptococcus and staphylococcal infections in man." Plummer<sup>55</sup> noted that, in a small series of pneumococcal pneumonias, the clinical results compared favorably with those obtained with sulfapyridine and sulfathiazole, and that in certain other infections, particularly those due to Friedländer's bacillus, the results were encouraging. In another paper, he<sup>9</sup> included 51 patients with pneumococcal pneumonia treated with sulfadiazine, with 9 deaths, or a mortality rate of 18 per cent, as compared with 69 deaths, or a rate of 12 per cent, among others treated with sulfapyridine, sulfathiazole or their congeners. Serum was used, in addition, in some of the cases treated with each of the drugs.

The 446 sulfadiazine-treated cases reported from the Boston City Hospital<sup>10</sup> included a variety of infections. Among them were 178 patients with pneumococcal pneumonia, of whom 19, or 11 per cent, died. This is the lowest mortality in any comparable group of cases previously reported from this clinic. The drug was also effective in pneumonias due to hemolytic streptococcus and

staphylococcus, in meningococcal infections, in acute infections of the upper respiratory tract, including sinusitis, in erysipelas, in acute urinary tract infections, particularly those due to the colon bacillus, and in acute gonococcal arthritis. So far as could be judged from the small numbers of cases, sulfadiazine appeared to be as effective as sulfapyridine or sulfathiazole in each of these conditions. Dingle, Thomas and Morton<sup>50</sup> also found sulfadiazine to be highly effective in the treatment of a small series of cases of meningococcal meningitis, including both the epidemic and the endemic forms.

### Toxic Effects

All the reports indicate that toxic manifestations from sulfadiazine are encountered much less frequently than with any of the other common sulfonamides. The toxic effects that were noted among the 872 cases reported by various authors<sup>10 44 53 55 56</sup> may be summarized briefly. Nausea and vomiting occurred in 94 per cent of the cases, dermatitis in 17 per cent, fever alone in 04 per cent, hematuria in 10 per cent, headache or vertigo in 06 per cent, and leukopenia in 18 per cent. Crystals were found in the urine in 117 per cent of the cases. The following manifestations were each mentioned by only one author and were not noted by the others: scleral and conjunctival injection was noted in 2 of Long's<sup>44</sup> 125 cases, and a questionable psychosis was noted in 7 of Flippin's<sup>15</sup> 100 cases. Nitrogen retention in the blood occurred in 11 per cent of our cases,<sup>40</sup> and one case of anuria, relieved by ureteral catheterization, was included. Another case of anuria, unrelieved by catheterization and ending fatally, has been observed more recently.

Long<sup>44</sup> has noted that, even in the face of grave kidney damage, the free and conjugated fractions of sulfadiazine seem to be more readily excreted by the damaged kidney than is usually the case with sulfapyridine and sulfathiazole, and this corresponds with our experience.<sup>40</sup> Anemia and cyanosis have not been observed in any of the cases. With respect to the cyanosis, it has been shown that carbonic anhydrase is not inhibited by sulfadiazine or by sulfathiazole, but it is inhibited by sulfanilamide, which caused this symptom so frequently.<sup>54</sup>

### Dosage

In general, sulfadiazine has been used in the same doses as the other sulfonamides. It is given orally whenever possible. The initial dose for adults is 4 gm, and this is followed by 1 gm every four hours until the temperature reaches normal; some prefer to continue this dose for one

or two days longer. It is then reduced to 1 gm. every six hours. Blood levels between 7 and 10 mg per 100 cc are maintained readily on this schedule in most patients who are on an adequate fluid intake (2500 to 3000 cc. daily). In patients who are comatose or vomiting severely, and in others who are extremely ill, it may be of advantage to give an initial dose of 5 gm of the sodium salt parenterally in the manner already mentioned. Follow up doses of 2 or 3 gm of the sodium salt may then be given at intervals of eight to twelve hours, preferably subcutaneously in 400 or 600 cc (0.5 per cent) of physiologic saline solution, but a shift to the oral route should be made as soon as possible.

### FAILURES AND SECONDARY FEVERS IN SULFONAMIDE-TREATED CASES OF PNEUMOCOCCAL PNEUMONIA

The factors influencing mortality have recently been analyzed in a group of 800 cases of adult pneumococcal pneumonia treated with sulfapyridine and sulfathiazole.<sup>50</sup> The most important factors were age and bacteremia. The mortality in the patients over forty years of age was 154 per cent, a rate almost four and a half times as great as that in those less than forty years old (35 per cent). The bacteremic patients had a mortality rate of 32.3 per cent, which was nearly five times as high as that in the patients with negative blood cultures (6.8 per cent). Late treatment was also an important factor. When treatment was started on the fifth day or later, the mortality (18.4 per cent) was almost three times as high as that in the patients in whom treatment was begun on the fourth day or earlier (5.6 per cent). The type of pneumococcus was also important. The death rate in the Type-3 cases was 20 per cent, as compared with 10.5 and 7.0 per cent in Type 1 and Type 2 cases, respectively, and 8.0 per cent in those due to other types. Complications of the pneumonia influenced the mortality appreciably, but much less than the presence of other associated severe diseases. The most frequent of the latter were heart disease and alcoholism. The mortality in the cardiac patients was 31.3 per cent, and among the alcoholics, 20.5 per cent. Sex and color had no appreciable effect on the mortality in these cases.

These findings are in essential agreement with the results of all other analyses of mortality in cases of pneumococcal pneumonia that have been recorded in the past. The same factors are equally important in patients treated symptomatically without the aid of specific measures, as well as in patients treated specifically with serums or chemicals, or both. It is not to be inferred, however, that old patients, those with bacteremia or with Type 3

pneumococcus infections and those with associated diseases, are not benefited by the therapy. The prognosis for recovery without specific treatment is very poor in such cases, but the reduction in death rate and the improvement in the clinical course resulting from chemotherapy are almost of the same order as among other cases.<sup>60</sup> This was clearly demonstrated recently for the old-age pneumonias. In one group of such cases, the mortality was reduced from an average of 75.0 per cent to 23.5 per cent by the use of sulfapyridine, and the average duration of fever was reduced from twelve to three days by chemotherapy.<sup>61</sup>

The causes of secondary fever among 339 sulfapyridine-treated cases of pneumococcal pneumonia were reviewed recently by Dowling and Abernethy.<sup>62</sup> Relapses of fever and symptoms of pneumonia occurred in 15 cases after apparent temporary improvement, but before the signs and symptoms had entirely cleared. In 7 of these cases, the dose seemed to be adequate, as judged by the high levels of the drug in the blood. Five of the cases, including 4 of the latter, were Type-3 pneumococcus pneumonias, and 3 of the 4 deaths among these 15 cases were in patients with this type. It is of interest in this connection that Type-3 strains have been found to respond less regularly to sulfapyridine therapy than Type-1 or Type-2 strains in experimental infections in mice.<sup>63</sup>

So-called "drug fever" occurred in 7 cases reported by Dowling and Abernethy. This diagnosis was based on the concomitant presence of a morbilliform rash in 3 cases, and on high fever, without signs of marked toxicity or in the absence of other demonstrable cause of fever, in the remaining cases. The drug fever began from two to four and one-half days after the crisis and continued for one and one-half to four days, regardless of whether administration of the drug was continued or stopped. All these patients recovered.

In 6 of Dowling and Abernethy's patients, a second attack of pneumonia caused by a different type of pneumococcus occurred while treatment with sulfapyridine was being continued and after apparent recovery from the original attack. All these patients recovered from the recurrence. Serum was used, in addition to sulfapyridine, in the first attack in 2 cases, and sulfapyridine was used alone in all the other attacks, except in 2 of the recurrences, in which only symptomatic treatment was given. Such recurrences have not been encountered previously by these authors in any of 65 patients who were treated symptomatically, and occurred in only 1 out of 120 cases treated with serum alone.

The fourth cause of secondary fever, according

to Dowling and Abernethy, was the occurrence of complications of the pneumonia. This accounted for 4 cases.

In the experiences with sulfathiazole referred to earlier, relapses and recurrences have been much less frequent than with sulfapyridine. On the other hand, drug fevers and rashes were considerably more frequent. Sulfathiazole fevers, with or without dermatitis, may be associated with severe symptoms, including chills, so that a relapse of infection or the occurrence of complications or of other intercurrent infections is suspected, but the pulmonary symptoms do not recur. It has been our experience that sulfathiazole fever, especially when accompanied by a rash, usually progresses under continued treatment and only rarely subsides before the drug is withdrawn.

#### CHEMOTHERAPY IN NONPNEUMOCOCCAL PNEUMONIAS

Most of the reports dealing with the chemotherapy of pneumonia and containing bacteriologic data have dealt primarily with pneumococcal pneumonias. Occasional cases of primary pneumonia due to other organisms are included. Sulfonamides have been used in such cases because of the known effectiveness of the drugs in other infections with the same organisms or because no other effective remedy is available. It is therefore difficult to assess the value of chemotherapy under such conditions. A few recent reports have dealt primarily with nonpneumococcal pneumonias and may be reviewed briefly.

##### *Streptococcal Pneumonia*

Lawrence and Sutliff<sup>64</sup> have recently summarized part of the experience of the New York City pneumonia-control program with respect to the role of hemolytic streptococci in pneumonia. During the winter of their study, 5.05 per cent of all sputum specimens examined in the health department laboratory yielded cultures in which more than 15 per cent of the colonies were hemolytic streptococci. In 15 of 141 patients from whom these specimens were obtained, there was no pneumonia. In 45 of the others, the streptococci were associated with pneumococci, and in the remaining 81 cases of pneumonia the streptococcus was the only significant organism.

The fatality rate for their entire series of 126 cases was 10.3 per cent. Only 22 of the cases were hospitalized, and 7 of the 13 patients who died were hospitalized. This makes a fatality rate of 6 per cent in the home-treated cases and 32 per cent in the hospitalized patients. Empyema occurred in only 3 per cent of all the cases and

in 18 per cent of those treated in hospitals. In 10 cases receiving adequate doses of sulfanilamide, there were no deaths; among 57 cases receiving less than the generally recommended doses of sulfanilamide, 8 deaths were reported, a fatality rate of 14 per cent; and of 59 patients who received no sulfanilamide, 4 died, a rate of 8 per cent.

Keefe, Rantz and Rammelkamp<sup>65</sup> studied 55 cases of hemolytic streptococcus pneumonia and empyema treated with sulfanilamide and sulfapyridine. There were 39 cases of pneumonia alone, and 14 of the other 16 cases had empyema, which followed an infection of the lung. The mortality rate in all the cases was 18 per cent, and it was the same whether or not empyema was present. Bacteremia occurred in 7 patients, of whom 4 died. In these cases, the use of sulfanilamide or sulfapyridine did not reduce the incidence of empyema, nor did it shorten the course of the disease. There was suggestive evidence that the fatality rate in both the cases of pneumonia and empyema was reduced by using these drugs. Four patients with empyema recovered following multiple aspirations of the chest, and chemotherapy. The best results, however, were obtained with a combination of chemotherapy and thoracotomy.

Carey<sup>20</sup> used sulfapyridine in the treatment of 42 infants and children with hemolytic streptococcus pneumonia, and also treated 21 such patients with sulfathiazole. The death rate in patients under two years of age was 26 per cent, and in those over two years old it was 6 per cent. After those who died within twenty-four hours were excluded, the death rate was 3 per cent in each group. There was no significant difference in the average duration of the disease after treatment with the two drugs used.

Sulfadiazine has proved highly effective in the few cases of hemolytic streptococcus pneumonia in adults in which it has been used.<sup>49, 40</sup> Of the 4 cases included in our report,<sup>40</sup> 2 had bacteremia and 2, including 1 of the latter, had empyema. All 4 patients recovered completely without operation.

### *Staphylococcal Pneumonia*

Although numerous reports are available of sulfonamide-treated cases of staphylococcal infections, particularly cases of staphylococcal sepsis treated with sulfathiazole, data concerning the effects of the drugs in primary pneumonias due to *Staphylococcus aureus* are very scant. Individual cases or groups of a few such cases are scattered among some of the reports dealing with the chemotherapy of pneumonia or of staphylococ-

cal infections. On the whole, the results of treatment with sulfanilamide or sulfapyridine have not been favorable except, perhaps, in individual cases. On the other hand, the results of sulfathiazole therapy have been encouraging.

Carey<sup>20</sup> included 15 cases of staphylococcal pneumonia in his series. The fatality rate was 50 per cent in infants under two years of age, if the patients dying within twenty-four hours of admission to the hospital are included. Sulfapyridine was used in 8 of the patients, all of whom died, whereas 5 of the 7 sulfathiazole-treated patients recovered. One of the sulfathiazole-treated patients died ten hours after entry to the hospital, whereas the other died after seven days of intensive treatment with this drug. Shulman<sup>66</sup> has recently reported 2 severe cases of staphylococcal tracheobronchitis in infants successfully treated with sulfamethylthiazole and sulfathiazole.

Our report on sulfadiazine therapy<sup>40</sup> included 29 cases of staphylococcal pneumonia. Positive blood cultures for *Staph aureus* were obtained from 3 of the patients, all of whom recovered. In addition to the staphylococcus, influenza bacilli were cultivated from 3 cases and hemolytic streptococci from 5, including a patient in whom the latter organism invaded the blood stream. There were 6 deaths (21 per cent) among the 29 cases, including the one with hemolytic streptococcus bacteremia. Fluid was obtained by thoracentesis in 6 of the patients who recovered. The original fluid and subsequent ones were all sterile in 2 of these cases. In the remaining 4, the original fluid was infected with staphylococci; 2 of these patients recovered completely following sulfadiazine therapy and thoracenteses, and the other 2 were drained by thoracotomy. A number of cases of staphylococcal pneumonia occurred during the past winter as complications of epidemic influenza, which was prevalent at that time. Except for some fulminating cases, these patients responded well to either sulfathiazole or sulfadiazine, although the course was frequently prolonged or associated with empyema or with abscess formation in the lungs.<sup>67</sup>

### *Friedlander Pneumonia*

The mortality in acute primary Friedlander pneumonia treated without specific agents is very high. Only 1 patient in 32 cases reported by Solomon<sup>68</sup> recovered, and all of 5 treated with serum died. In Bullowa's<sup>69</sup> first series, there were 7 recoveries among 41 cases, a mortality of 83 per cent. Among the 24 cases in his series that were due to the Type A Friedlander bacillus, 6 patients received type-specific serum, and 3 recov-

ered, whereas only 1 recovered among the 18 who were treated without specific serum. More recently, Solomon<sup>70</sup> reported a group of 17 cases of chronic Friedländer bacillus pneumonia. Sulfapyridine was used in 4 of these patients, all of whom recovered, although pulmonary suppuration continued without apparent effect. One of these patients had a positive blood culture. Another bacteremic patient was treated with sulfanilamide and recovered, although he, too, contracted lung abscesses. Among the 12 patients treated without sulfonamide drugs, there were 4 deaths, but 2 of those who recovered had positive blood cultures. More recently, Perlman and Bullowa<sup>71</sup> presented a second series of 37 cases of primary Friedländer pneumonia, with a mortality of 84 per cent. Among these patients, 9 were treated with sulfanilamide or sulfapyridine, and 6 died; 7 received these sulfonamides in addition to specific serum, and only 1 recovered; 13 with Type-A infection received specific serum alone, and all died; and of 8 who were given only symptomatic treatment, 2 recovered.

These reports indicate that treatment with sulfanilamide or sulfapyridine may be successful in individual cases, but the results as a whole are not very favorable. Reports of sulfathiazole-treated cases are still too few to evaluate. However, the greater effectiveness of sulfadiazine in experimental Friedländer-bacillus infections<sup>45</sup> suggests that one may look forward to better results from this drug.

### *Pneumonias of Undetermined Etiology*

Recent reports concerning chemotherapy in pneumonia include a considerable number of cases in which the bacteriologic studies fail to yield pneumococci or other organisms that might be considered etiologic. In many of these cases, the predominant organism obtained from direct cultures of the sputum is either *Streptococcus viridans* or a nonhemolytic or slightly hemolytic (alpha) streptococcus. The relation of such streptococci to the disease is difficult to evaluate, although in rare cases they seem to be significant, since they are also obtained in cultures of the blood or of pleural exudate and are frequently cultivated from the lungs at autopsy. Some of these cases have all the clinical features of typical lobar pneumonia, whereas others have atypical lesions and symptoms. Most of these patients apparently respond well to sulfonamides. Among 52 cases treated with sulfadiazine, there were 3 deaths, and all the fatal cases were in patients over sixty years old who had atypical pneumonias.<sup>40</sup> It is possible that many of the cases in this category,

particularly those with typical lobar pneumonia that respond so well to chemotherapy, are cases of mild pneumococcal pneumonia in which the causative organism escapes detection. Other cases of atypical pneumonia in which the patients fail to show any clinical response but nevertheless eventually recover may be due to viruses as yet unidentified.

Attention was called recently to a group of atypical pulmonary infections complicating severe and intractable bronchial asthma or congestive cardiac failure. The bacteriology in these cases is often unrevealing. Proper treatment of these cases with sulfathiazole or sulfadiazine may not only result in prompt improvement in the pulmonary infection, but may also render the underlying condition more amenable to appropriate treatment.<sup>72</sup>

## CASE RECORDS OF THE MASSACHUSETTS GENERAL HOSPITAL

ANTE-MORTEM AND POST-MORTEM RECORDS AS USED  
IN WEEKLY CLINICOPATHOLOGICAL EXERCISES

FOUNDED BY RICHARD C. CABOT

TRACY B. MALLORY, M.D., *Editor*

### CASE 27311

#### PRESENTATION OF CASE

A thirty-year-old housewife entered the hospital complaining of generalized aches and pains.

The patient felt well until five years before admission, when a rather severe, sharp pain developed in her left knee; this was aggravated by motion. Six months later, a tender swelling appeared above this joint; and the pain extended to her left hip and lower back, and another swelling developed in the right tibia. Approximately one year after the onset of her symptoms, several bone cysts were said to have been removed from her jaw. Three years before entry, and without untoward symptoms, the patient gave birth to a normal child by forceps delivery; during her confinement she suffered from severe pyorrhea. Shortly afterward, the back pain became severer and spread to the thoracic spine, sternum, left shoulder and lower left ribs, where another tender swelling developed. At that time the patient entered an outside hospital, where her complaints were generalized aches and pains, polyuria and polydipsia. Examination revealed bilateral exophthalmos and small painless swellings over the mandible and tibia. X-ray study showed areas of decreased density in the skull and jaws, with a large cystic growth in the right tibia. An intravenous pyelogram demonstrated a calculus in the left ureter, with no dye from the right kidney. The blood calcium was 13 mg., the phosphorus 2.8 mg. per 100 cc. and the basal metabolic rate +9 per cent. A bilateral cervical exploration for a parathyroid tumor was performed without success. Two weeks later, an air injection into the mediastinum revealed no tumor, and subsequent exploration of the anterior mediastinum was fruitless. The patient was discharged from the hospital for a rest period, with a view to re-exploration. Several weeks later, however, she visited her own physician and complained of nervousness. A thyroidectomy was thereupon performed, but the apparent benefit derived from this procedure was short lived and her aches and pains returned, with pronounced tenderness over the tumor sites.

During the period between two years and one

year before admission, the patient suffered from severe headaches, most marked in the right temporal region, with tenderness in the entire calvarium; and for the previous eight months she had been forced to remain in bed, not from weakness, but because of pain.

Six months before admission, the patient entered a clinic, where another parathyroid exploration was unsuccessful.

At the time of admission to this hospital, in addition to her other symptoms, she complained of chest pain aggravated by deep breathing and coughing. There had been no loss in weight. A frequency of urination, with a nocturia of one to three times, had been present for about five years.

The family history was irrelevant. The patient had had the usual childhood diseases. She was in the habit of drinking a quart of milk each day.

On examination, the patient exhibited a yellowish pallor and was chronically ill, but in no obvious distress except on moving or being moved, when pain was apparent. There was exophthalmos, and the skin was dry, with slight hirsutism of the face and chest. The nose and throat were normal. There were numerous irregular, tender swellings over the scalp, mandible, seventh cervical spine, left clavicle, left lower-chest wall in the midaxillary line, both tibias at their upper ends and the middle of the left femur. Moderate tenderness on pressure was present over both crests of the ilium, more marked on the left. The heart was slightly enlarged, with a blowing systolic murmur best heard in the pulmonic area and along the left sternal border; the blood pressure was 110 systolic, 70 diastolic. The lungs were normal. There was moderate tenderness, without spasm, in both lower quadrants of the abdomen. Pelvic examination was negative.

Examination of the urine showed a specific gravity between 1.008 and 1.028, with ++ to ++++ tests for albumin. The sediment was often "loaded" with white blood cells and occasionally with red blood cells. A phenolsulfonephthalein test showed 5 per cent excretion in fifteen minutes and a total of 20 per cent in half an hour. Repeated, there was a 15 per cent excretion in thirty minutes and a total of 25 per cent in an hour. Numerous Sulkowitch tests for urinary calcium varied from + to +++.

The blood showed a red-cell count of 2,300,000 with a hemoglobin of 55 per cent, and a white-cell count between 6000 and 14,000. A stained film was normal, and the reticulocyte counts varied between 2.0 and 5.2 per cent. The sedimentation rate was 8 mm. in one hour, the prothrombin time 40 seconds (normal, 20 seconds), and the hemato-

crit reading 37.5 per cent. The nonprotein nitrogen of the blood serum was 29 mg, the cholesterol 59 to 100 mg., the calcium 145 mg, the phosphorus 21 mg, the phosphatase 11.8 Bodansky units, and the protein 6.2 gm per 100 cc. The chlorides were 110.9 milliequiv, and the carbon dioxide combining power 22.8 milliequiv per liter. The serum van den Bergh was 2.1 mg. per 100 cc, biphasic; a bromsulfalein test showed 50 per cent retention; and a Congo red test showed 90 per cent retention of the dye in the serum. A gastric analysis showed free acid; the stools were normal. The basal metabolic rate was +32, +19 and +24 per cent on three occasions.

X-ray films of the bones showed a large defect in the skull in the right frontoparietal region, and a smaller defect in the upper frontal region. The entire calvarium was grossly thickened, and the margins of the inner and outer tables were obliterated. The bones showed a generalized decalcification, with large cystlike areas of rarefaction in the iliums, femurs, bones of the pelvis, ribs, scapulas and humeri. There was extensive rarefaction of the upper shaft of the left humerus, with destruction of the cortex on the lateral aspect. The bones of both forearms and hands showed changes similar to those in the other bones. An area of increased density was present in the distal extremity of the left radius, and a similar area in the distal extremity of the humerus. The lesions in the ribs and the upper extremity of the left tibia and both iliums showed marked thinning of the cortex, with expansion of the bones. The left acetabulum was thin, with intrapelvic protrusion of the left side of the pelvis in the region of the acetabulum. The vertebrae showed increased density in contrast to the other bones, and the trabeculations were irregular. Pathologic fractures were present in the second and the third lumbar vertebra, and the body of the fourth lumbar vertebra showed marked decalcification. The bones of the right foot showed decalcification, and there was a cystlike area in the distal extremity of the tibia.

With an intravenous pyelogram, the kidneys were obscured by gas in the intestine. There were two areas of calcification in the mid abdomen, and one overlying the sacrum, all of which had the appearance of calcified lymph nodes. There was also a 2-cm oval area of calcification overlying the transverse process of the fifth lumbar vertebra on the left, approximately in the course of the ureter. This shadow was somewhat denser and more smoothly rounded than the other shadows. Intravenous dye appeared on the right, and the kidney pelves and calyces appeared normal. There

was no evidence of excretion of the dye on the left.

Fluoroscopy and barium in the esophagus failed to outline a pathologic mass in the upper mediastinum. Laminograms of the anterior mediastinum failed to show evidence of disease.

X-ray films of the bones taken at another hospital three years previously showed that the osteoblastic areas present at that time in the lower radius and right tibia were typical benign giant-cell areas.

An electroencephalogram was normal.

On admission, the patient was very ill, and on the fourth hospital day a 500 cc blood transfusion was given. At the end of a week, a biopsy was taken from the left ilium.

#### DIFFERENTIAL DIAGNOSIS

DR WYMAN RICHARDSON: "Three years before entry, and without untoward symptoms, the patient gave birth to a normal child by forceps delivery; during her confinement she suffered from severe pyorrhea." Just what that means, I am not sure. It may mean that pre-existing bone disease was aggravated by pregnancy and resulted in pyorrhea. "... another parathyroid exploration was unsuccessful." I do not know where they looked for it. I am interested in knowing whether the sternum was split.

DR TRACY B. MALLORY: It was—on at least one occasion.

DR RICHARDSON: There is no record of the temperature. I assume that it was normal.

DR OLIVER COPE: The patient did have a little fever, but seldom more than a degree above normal.

DR RICHARDSON: "X-ray films of the bones taken at another hospital three years previously showed that the osteoblastic areas present at that time in the lower radius and right tibia were typical benign giant-cell areas." Do you know what that means, Dr Lingley, or should I ask you?

DR JAMES R. LINGLEY: The cystic areas spontaneously filled in with new bone, which is unusual. I suspect that the patient had a fracture.

DR RICHARDSON: I do not consider myself an expert on bone diseases. However, I shall try to see what I can do. There are four things that one should try to explain: bone disease, liver disease, as shown by the bromsulfalein retention; bone marrow disturbance, as evidenced by the severe degree of anemia; and kidney disease.

I shall start with bone disease. Perhaps we might look at some of these lesions, if Dr Lingley will be so good as to show the films. I particularly want him to tell me if the lamina dura is absent.

DR. LINGLEY: This is a generalized condition of bone characterized by multiple large cystlike areas of destruction. The process is most extensive in the pelvis, where one can see tremendous cystic areas in both iliums and intrapelvic protrusion of the acetabulum. In the spine, the decalcification involves the central portions of the vertebrae more than the margins, so that the margins appear denser in contrast. Some of the vertebrae show pathologic fractures. In the lower extremity of the radius, there is one area of increased density. The process is otherwise one of decalcification. The new-bone formation in this one area may have been due to a healed fracture. The process in the skull is characterized by generalized thickening of the calvarium and a large area of destruction in the frontoparietal region.

DR. RICHARDSON: The patient had teeth, and the lamina dura was absent. Is that not true?

DR. LINGLEY: Yes; and I did not mention an area of calcification in the region of the left ureter. That has the appearance of a calculus. The kidney is nonfunctioning on the left side.

DR. RICHARDSON: In regard to the bone disease, it is evident that this patient had overactive parathyroid tissue. The serum calcium was high, the phosphorus low. The phosphatase of 11.8 units seems to me to be a low figure in view of the degree of bone involvement, and that bothers me a little. However, I cannot see how you can get this picture with any widespread tumor process, and I therefore think it is a parathyroid effect. The fact that she was thoroughly explored and no adenoma found does not, I believe, rule out the possibility that one of these tumors was hidden and not found.

The next question to be considered is whether this might have been some type of secondary hyperplasia of the parathyroid glands, but I cannot see any good reason for such secondary hyperplasia and I have to rule it out. Therefore, I should say that this patient had primary hyperparathyroidism, probably due to a parathyroid adenoma, and that one should continue looking for it.

There are other things that are more difficult for me to explain. She had a marked anemia, apparently of a macrocytic type, with some evidence of reticulocyte increase. If one were to look at the blood smear, one would probably find evidence of bone-marrow activity. I do not recall an anemia of that type associated with parathyroid disease, and it seems to suggest that there is more evidence of encroachment on the bone

marrow than would be explained by cystic changes such as she showed. I do not see why disease of the bone of this type should interfere with marrow function to this extent, and I am bothered by that. I shall go back to it in a minute.

In regard to the liver, the serum van den Bergh was slightly above normal, and there was 50 per cent retention of bromsulfalein, so that there is evidence of some disturbance of hepatic function. We know this patient had a renal stone, presumably because she had been excreting so much calcium. One kidney is said not to have excreted any dye. On the other hand, excretion of phenolsulfonephthalein dye was fairly good, considering the renal function as a whole—20 per cent in half an hour, and 25 per cent in another test; function was definitely impaired, but not markedly so. The urine could be concentrated up to 1.028. At the same time, the patient had marked albuminuria, and the blood pressure was 110 systolic, 70 diastolic. There was no hypertension. She was entitled, of course, to some kidney infection along with the stone. It seems to me that the renal picture, with that degree of albuminuria, with normal blood pressure and with normal nonprotein nitrogen, is the picture one sees with nephrosis. If one considers that as a possibility, one begins to wonder whether there was some other condition that involved the kidney, the liver and the bone marrow. A Congo red test gave 90 per cent retention of the dye. If one considers it specific for amyloid disease, one would have to say that for some reason this patient had amyloid disease. Usually, of course, amyloid disease is associated with infection, and I cannot make out that this patient could have had a long-standing infection. I do not see any reason to consider amyloid disease.

DR. COPE: I should have spoken up sooner. Ninety per cent of the dye was still found within the serum. We considered it normal.

DR. RICHARDSON: The Congo red test, then, is against amyloid disease, and it is foolish to talk about it anyway. As a matter of fact, I do not consider the Congo red test to be worth anything. It may possibly be valuable when 90 per cent, or so, of the dye is taken up. However, since I can think of no other explanation of hepatic involvement, I raise a question of amyloid disease.

I shall leave my discussion there and say that this patient had primary hyperparathyroidism probably due to adenoma, with secondary renal calculus and bone changes.

DR. J. H. MEANS: I should like to know more about the thyroid situation. There is just enough given here to be tantalizing, but hardly illuminat-

ing. It is a mystery why they took out the thyroid gland, why the patient had exophthalmos, and why the metabolic rate went up rather than down after thyroidectomy.

DR. RICHARDSON: I meant to mention the exophthalmos. I wonder if she had always been a little exophthalmic; and if not, could it not have been due to some lesion in the orbit?

DR. FULLER ALBRIGHT: She had an unusually thick skull.

DR. LINGLEY: There is thickening of the bones all around the orbits. I do not see any reason why that might not be the cause of the exophthalmos.

DR. RICHARDSON: As for the basal metabolic rate, I wonder whether it was basal. She had a severe anemia and a fever.

DR. ALBRIGHT: I believe they took out the thyroid gland in looking for the parathyroid tumor. They thought it might be in the thyroid gland.

A PHYSICIAN: How do you explain the continuous severe headaches?

DR. RICHARDSON: There was enough bone disease to account for that. Is it true that people with high blood-calcium levels have headaches?

DR. ALBRIGHT: I do not believe so.

A PHYSICIAN: Was a lumbar puncture ever done?

DR. COPE: She could not be rolled over. It was very difficult even to take x-ray pictures. She was very ill, and the plates were taken one or two at a time.

DR. WILLIAM B. BREED: Could the large skull lesion account for the headaches?

DR. ALBRIGHT: Yes; it most certainly could. There is a huge blood supply to this type of lesion.

We came to the same conclusion as Dr. Richardson, with exactly the same misgivings. There were four reasons why we were puzzled. In the first place, the patient had been operated on at two excellent clinics and no tumor had been found. That is only a fairly good reason. Secondly, the skeletal x-ray films showed localized areas of normal bone density. One can have a patient with hyperparathyroidism and no bone disease, but if there is bone disease it should be generalized. Dr. Cope finally explained these areas by going back to previous x-ray films and finding that there had been cysts in these same areas. Thirdly, we were also disturbed about the phosphatase. It was high, but not so high as we should have expected for the degree of bone disease. But the thing that disturbed us most of all was the anemia. When one meets bone disease with anemia, one worries, of course, about some bone-marrow tumor. However, a bright thought was finally brought forth to

explain the anemia. After all, this patient was a mass of giant-cell tumors. These are very vascular lesions and have many hemorrhages into them. This gives them their characteristic brown color, which is due to changed hemoglobin. We, therefore, finally concluded that her anemia was due to blood loss into her bones.

DR. RICHARDSON: The anemia as described could not be due to chronic blood loss.

DR. ALBRIGHT: I wonder if the figure for the hematocrit is correct.

DR. MALLORY: There are two figures recorded here—a hematocrit of 20 per cent, corresponding to a red-cell count of 2,300,000, and one of 37.5 per cent, going with a red-cell count of 3,400,000. The second pair of figures followed several transfusions.

DR. RICHARDSON: The hematocrit was approximately normal then, whereas an anemia due to blood loss should be definitely microcytic and hypochromic. Is there a description of the blood smear?

DR. ALBRIGHT: Dr. Bernard M. Jacobson reported normocytic, normochromic red cells and no immature red or white cells except for the reticulocytes, which were always high varying from 2 to 5 per cent. The serum van den Bergh was a little high, 2.0 mg., and the urobilinogen was increased, a finding suggesting increased blood destruction.

DR. RICHARDSON: The blood picture as reported by Dr. Jacobson is nonspecific, and without examining the smear myself I hesitate to make further comment.

DR. COPE: Dr. Albright comforted me a great deal by being worried, because we certainly were worried. It is fair to emphasize that, in addition to the increased bone density in the three areas, the patient had four huge giant-cell tumors of a size that we have not encountered in any other patient with hyperparathyroidism. It occurred to us that perhaps she had malignant bone disease originating in the giant-cell tumors, and I hope that Dr. Mallory will discuss this, because roughly 7 per cent of the benign giant-cell tumors of adolescence become malignant. We have not, curiously enough, encountered the development of bone malignancy in any of the areas of microscopically similar giant-cell tumors in hyperparathyroidism. Patients with hyperparathyroidism may have hundreds of these tumors.

In the x-ray films, the large tumor areas appear to be cystic. When we cut down on the one in the ilium, it was a huge solid tumor like a very stiff sponge, very vascular, with a thin cortex of bone. We were interested to know

tune and eating very little. The question is whether a quart of milk a day would be sufficient to produce the necessary extrinsic factor for blood formation. It might be a macrocytic anemia due to the lack of the food factor described by Castle \*

DR ALBRIGHT. But she had reticulocyte response

DR RICHARDSON: That is the feature of myelophthisic anemia. Such patients have reticulocytes, nucleated red cells, polychromatophilia and so forth

DR ALBRIGHT. I shall have to read my book again

## CASE 27312

### PRESENTATION OF CASE

A fifty-three-year-old woman entered the hospital complaining of "dizzy spells"

The patient felt well until the birth of her first child, sixteen years before admission. Ever since that time, she had suffered from attacks of weakness and palpitation and from a sensation of fainting. The attacks lasted ten to fifteen minutes, came on in any position and at any time, and were relieved by lying down. One year after the onset, the patient was admitted to a hospital for three months, where a diagnosis of cancer was made and x-ray treatments were given to her left chest. This resulted in complete relief for the next five years, at the end of which time the attacks reappeared. Sixteen x-ray treatments were directed at the same region in her chest, and again there was relief and she was "able to breathe better." The patient then felt well until eight months before admission, when the "spells" recurred. She consulted her physician, who said that her "left chest had filled up again," and subsequently sixteen x-ray treatments were given. This time, there was no relief, and operation was advised. At no time had there been pain, cough, hemoptysis, dyspnea, orthopnea, edema, nausea, vomiting, tarry stools or loss of weight.

The family history and past illnesses were irrelevant

On examination, the patient was well developed and well nourished and in no distress. The left border of the heart could not be made out, but the organ was displaced to the right. There were no murmurs, and the rhythm was irregular, without pulse deficit, the blood pressure was 140 systolic, 84 diastolic. Examination of the lungs

showed dullness to percussion, absent tactile and vocal fremitus, and absent breath sounds over the entire left chest anteriorly from the level of the first rib down and posteriorly from the level of the third dorsal vertebra.

Examination of the abdomen and nervous system was negative.

The temperature was normal, the pulse 94, and the respirations 23

The urine gave a + test for albumin. The blood showed a red cell count of 4,340,000 with a hemoglobin of 13.0 gm (photoelectric cell technic), and a white cell count of 16,600. A blood Hinton reaction was negative.

An x-ray film of the chest showed an unusually large mass occupying the lower three fourths of the left side of the chest and displacing the heart shadow to the right. The upper margin of the mass was sharply defined and smoothly rounded, without lobulations, and the greater portion of the tumor lay anteriorly. It was homogeneous in density, and no areas of calcification were seen within it. The right lung field was clear.

A barium swallow showed the esophagus to be displaced to the right along with the heart shadow. The mass itself, however, did not appear to extend as far medially as the esophagus.

On the seventh hospital day, an operation was performed.

### DIFFERENTIAL DIAGNOSIS

DR RICHARD H. SWEET: There were no symptoms referable to her chest, hence, we are dealing with a mediastinal tumor, and I presume that much of the differential diagnosis depends on the examination of the x-ray films. May we see them, Dr Hampton?

DR AUBREY O. HAMPTON: All these films were taken within three days, so that we had no time control. The mass does lie anteriorly. Although you probably cannot see it from your seats, this is the posterior margin, very sharp and smooth. Variation in position of the patient did not seem to change the shape of the mass. It remains at about the same level in all the films. It does not seem to move with respiration. The esophagus is displaced, and the visible portions of the lungs are perfectly normal. There is no evidence of disease in the ribs or spine. We cannot see the anterior ends of the ribs very well, and a mass lying anteriorly might involve them without showing. I do not believe that is the case here. The ribs are thin, as they often are in this area, but they are not separated.

DR SWEET: The history is puzzling because of its long duration and because of the statements

\*Castle W. B., Townsend W. C. and Heath C. W. Observations on the etiology relationship of achylia gastrica to pernicious anemia. III. The nature of the reaction between normal human gastric juice and beef muscle leading to clinical improvement and increased blood formation similar to the effect of liver feeding. *Am. J. M. Sc.* 180:305-335, 1930.

made about the benefits obtained from x-ray treatment. I cannot believe that the patient had anything that should have been treated by x-ray sixteen years ago. If she had cancer at that time, as the record suggests, she would not be alive and well sixteen years later, either with or without x-ray treatment. So that I doubt very much if she had cancer sixteen years before she came in. For the same reason, I also doubt very much if she had lymphoma at that time, although some tumors of the lymphoma group do survive for relatively long periods. Furthermore, I do not understand why x-ray treatments given sixteen years ago afforded relief from her dizzy spells, palpitation and sensations of fainting. Nor is it easy to explain the ten-year period of freedom from symptoms before there was a recurrence, once again with relief after x-ray treatment. I am forced to conclude that the dizziness and related symptoms bore no relation to the mediastinal tumor, and that x-ray treatment of the chest to relieve them was irrational.

It seems to me that in the differential diagnosis we must first exclude a chest-wall tumor. The x-ray films do that satisfactorily. The physical signs are those of tumor. The films suggest that it is a solid tumor, and one can fairly well exclude tumor of the lung, because of the lack of symptoms and because of the x-ray findings. We therefore have to assume, if we exclude these two sources, that this tumor arose primarily from the mediastinum, although it has pushed into the left chest rather far. The heart and other mediastinal structures have been pushed to the right. The statement is made, and it seems apparent from the x-ray films, that the tumor was in the anterior part of the chest, although it has grown posteriorly to some extent. I assume it did not arise in the posterior part. Solid or cystic tumors arising in this region are relatively few, as you know. We have seen tumors—not of this size, in my experience—arising from the thymus. Last summer, we had a dermoid cyst in the mediastinum arising from thymus remnants, but that was no bigger than a baseball. This is too big to be a thyroid tumor. I suppose lymphoma might be mentioned, but it does not look to me like lymphoma, in spite of the long history and the relief after x-ray therapy. It could be a dermoid cyst. It shows no calcification, but that is not necessary by any means. If it had arisen from the posterior mediastinum, we should have an excuse for mentioning neurofibroma, since tumors of that group commonly occur in the posterior mediastinum. At any rate, although I cannot make a definite diagnosis of what the tumor is,

I should say it was a solid or cystic tumor, and that the patient ought to be operated on.

DR. TRACY B. MALLORY: Dr. Bland, you saw this patient in relation to the attacks of dizziness and fainting.

DR. EDWARD F. BLAND: For fifteen years, she had had paroxysmal attacks of rapid heart action, which I assume were responsible. On examination, I did not find anything wrong with her heart. Later, she had an attack of tachycardia that lasted fifteen minutes, but when I saw her, her heart action was again normal, the blood pressure was all right, and her condition was good. I ordered 3 gr. quinidine, three times a day, as a prophylactic measure.

DR. RALPH ADAMS: As Dr. Churchill's associate, I saw this patient and believed preoperatively that she had a dermoid cyst. I also thought of teratoma.

DR. EDWARD D. CHURCHILL: We had the advantage of seeing an x-ray film taken five years previously, which was apparently identical with the ones you see here. Several needle aspirations had been attempted, but her physicians never obtained anything but blood, so that we did not try thoracentesis. We were faced with a rather difficult situation in regard to indications for operation because this woman was getting along quite well except for her attacks of dizziness. It was known that the mass had been present for at least five years, and she was fifty-three years of age. She had been prepared for operation in another city, but a heart attack led to cancellation of the program. Our line of reasoning was a good deal the same as that in a case of dermoid cyst presented here a few weeks ago. That is, this patient was reaching an age at which she might be expected to have more frequent symptoms related to her heart, and for the rest of her life her medical advisers would face the dilemma whether to take the tumor out or to let her carry on and accept any cardiac embarrassment that the tumor might be causing. Also, it was impossible to disassociate symptoms that might arise from intrinsic heart impairment and heart action disturbed by the presence of the huge tumor. However, we assured her physician that we reserved the privilege of making a dignified retreat if we thought the removal of the tumor would in itself be too hazardous. In other words, we did not want to assume a foolish risk with an eye on the trophy because of the relatively comfortable life that this woman was able to lead. When we did open the chest, it was found that the tumor was readily resectable. She made an uneventful recovery. I do not believe we made a definite preoperative

diagnosis—any more definite than that made by Dr Sweet

DR ADAMS 'Excision of mediastinal tumor is written on the operative sheet. As we discussed it preoperatively, I believe we learned toward termination

DR MALLORY Can you describe the location of the mass at operation?

DR CHURCHILL It seemed to be from the anterior mediastinum. It filled the whole hemithorax.

DR MALLORY Could it have arisen from the sympathetic chain?

DR CHURCHILL No, it was too far anterior. The phrenic nerve was displaced backward by the tumor.

#### CLINICAL DIAGNOSIS

Mediastinal tumor

#### DR SWEET'S DIAGNOSIS

Benign tumor of the anterior mediastinum (possibly dermoid cyst)

#### ANATOMICAL DIAGNOSIS

Perineural fibroma

#### PATHOLOGICAL DISCUSSION

DR MALLORY The tumor, as is of course obvious from the x-ray films, was an extremely large one. Its whole central portion was necrotic—a mass of dead tumor tissue and hemorrhage, around which lay a rim of viable tumor of varying thickness. There were some spots that looked yellow in gross, and one area almost suggested the membranous lining of a cyst so that the question arose whether it might be a dermoid. On microscopic examination, however, it is quite obvious that it is a fibromatous tumor and equally obvious that it is of neurogenous origin, in fact, one might, I believe, classify it as schwannoma, although

such tumors do not usually grow to this size or show necrosis in the center. The outlook I think is good. It is unlikely that there will be a recurrence.

DR CHURCHILL It is not a malignant tumor?

DR MALLORY I should say not. Our original impression, I confess, was fibrosarcoma.

DR CHURCHILL Have you taken several sections in varying parts to be sure that there was only one germ layer involved?

DR MALLORY We have gone back to the gross specimen and picked more suspicious areas from that point of view, and found no other form of tissue. The tumor is obviously of nerve sheath origin.

DR HELEN S. PITTMAN Then it could not have responded to x-ray therapy?

DR MALLORY It seems improbable.

A PHYSICIAN Where did it arise?

DR MALLORY There are sympathetic nerves everywhere, and it did not have to arise from a grossly namable one.

DR BLAND Have the attacks of rapid heart action been less frequent since the operation?

DR CHURCHILL I have not had a follow up report yet.

DR BLAND In one attack during her hospital stay, we were able to get an electrocardiogram, which showed that her rapid heart action was due to auricular flutter. Several of the recent cases of flutter we have recorded have been in patients who have had something seriously wrong in their chests and have been operated on.

DR CHURCHILL It comes as a postoperative complication not infrequently.

DR ADAMS Of the four cases of flutter that Dr Bland and I have been thinking of, two occurred in association with anterior mediastinal tumors, one in a thoracoplasty in which the apical adhesions had required considerable dissection anteriorly, and the fourth in a case of lobectomy for bronchiectasis.

## WARTIME TRANSFUSION THERAPY

EVEN war has its mitigations. In the present carnage, it is probable that much will be learned regarding surgical shock and its treatment by the injection of blood or one of its components.

Ten or fifteen years ago, certain Russian investigators drew blood from healthy cadavers; this was citrated, stored and given to patients, with good results. The possible value of this maneuver on the battlefield was obvious. Stored citrated blood obtained from healthy living persons was also used with success; the war in Spain proved that the method could be adapted to use on a large scale. During this period, the British medical journals began to publish numerous articles dealing with blood banks, and long before the present

war began, the British medical profession had prepared for trouble by equipping each section of London with a decentralized blood bank and a supply of volunteer donors. In this country, the first successful blood bank was organized a few years ago at the Cook County Hospital in Chicago, and since then, a number have been in successful operation.

For a hospital of at least two hundred beds in which there is a fairly large volume of surgery and obstetrics, the blood bank is very useful, particularly to the overworked intern. The bank, nevertheless, has its limitations. Blood gradually deteriorates even when stored at 2 to 4°C.: the immune bodies and prothrombin diminish considerably, the leukocytes and platelets disappear quickly, and the red cells become spheroidal and thus readily broken up in the circulation. For these reasons, fresh blood is distinctly preferable in the treatment of blood dyscrasias, chronic anemia and those acute infections in which the antibody or prothrombin content of the injected blood may be of some importance. Furthermore, transfusion reactions appear to be commoner with bank blood, and there is still the necessity for typing and cross-matching.

During the last year or two, the value of serum or plasma transfusions has been clearly demonstrated. For surgical shock, in which the symptoms are chiefly due to the loss of plasma from the circulating blood, it is of the utmost importance to inject intravenously a substance that remains in the circulation. The red blood cells are not needed, unless there has been serious hemorrhage, and blood serum or plasma is the ideal material. Furthermore, the use of pooled serum or plasma has several advantages. In the first place, it can be transported easily and stored for long periods—practically indefinitely in dried form. Secondly, since pooled samples lose their blood-group characteristics, it can be given quickly and indiscriminately, without wasting time for typing and cross-matching. Thirdly, it can be injected, if desired, in two or three times its normal concentration. Appreciating these facts, the

British Red Cross appealed last summer to the American Red Cross for a supply of plasma, and up to February of this year, when plans had been perfected for obtaining the supply in England, the American Red Cross, in co-operation with the Blood Transfusion Betterment Association, collected and shipped approximately 15,000 pints of liquid plasma

With the shipments to England ended, the American Red Cross, at the request of the Surgeons General of the United States Army and Navy, has now undertaken to provide a national reservoir of blood plasma for emergency use. It is being prepared in two forms: ordinary fluid plasma and dry, powdered (lyophilized) plasma, which is made ready for immediate use by the addition of sterile distilled water. Thus, thanks to the American Red Cross and affiliated agencies, the Army and Navy will have available quantities of plasma, ready for instant use

For the treatment of anemia, leukopenia and thrombopenia and of infectious processes, fresh blood obtained directly from healthy donors is still preferable. For emergency use in surgical shock, even when accompanied by a moderate amount of hemorrhage, plasma is probably as useful as whole blood. Thus the importance of a bank for storage of whole blood will probably diminish as dried plasma becomes commercially available

Blood in "tin cans"! Thus does science advance even as moral values reach low ebbs. The American Red Cross is to be congratulated for its sponsorship of still another humane project, which will certainly find its ultimate value in days of peace

## HANS BERGER

HANS BERGER,\* one of the foremost neuropsychiatrists of our time, discoverer of the electrical waves of the human brain, died on July 7, in Jen<sup>a</sup>, at the age of sixty eight. His important contribution to medicine, when first reported in 1929,

was considered by many as ludicrous. In the last ten years, however, it has been shown not only that his discovery was sound, but that, because the rhythmic, electrical discharge is altered in various normal and abnormal mental conditions, particularly in epilepsy, a new and highly significant technic, electroencephalography, had been made available for neurologic and psychiatric investigation.

To some of his contemporaries, this great achievement seemed like a stroke of luck, but viewed in terms of his earlier work and his life method it was the end result of a long and persistent search. From his days as a *Privatdozent* onward, he was a determined experimentalist. He proceeded on the assumption that the brain is a physicochemical machine, of which the chief product is behavior; and he was continually looking for what he called the physical concomitants of mental activity. His first studies were on the cerebral pulse, and he used its wave form and the interval between it and the apex beat to indicate the state of the cerebral vascular bed. Two of his early books, *The Intracranial Circulation* (1901) and *Organic Manifestations of Mental States* (1904-1907), contain reports of this work. His experiments on cerebral circulation were by no means impressive, but this was largely because no major changes in cerebral blood flow occur in association with the conditions he studied, namely, mental work, fright, sleep and states initiated by various types of sensory stimuli. These facts could not have been proved from deductive reasoning

Berger next turned his attention to the study of the temperature of the brain, and again he failed to find important correlations. Despite these negative results, three books, entitled *Studies on the Temperature of the Brain* (1910), *Trauma and the Psychoses* (1915) and *Localization in the Cerebrum* (1927), revealed in his work a persistently physiologic point of view

In 1924, at the age of fifty one, when many determined experimenters weaken and lapse into speculation, Berger started his epoch making work

\*An exhibit of material depicting Berger's discovery is now on display in the rotunda of the Boston Medical Library through the kindness of Dr. Frederic A. G. Lila

on the electrical activity of the brain. His search for electrical accompaniments of mental activity was, as a matter of fact, a return to a youthful line of investigation that he had started in 1902.

The significance of Berger's discovery was vaguely grasped by Adrian and Matthews, in England, in 1933, and the name, "Berger's rhythm," was given to the electrical discharge of the brain by the same authors in 1934. They, erroneously, thought that the waves originated in the occipital lobe and were identified with vision. By 1936, electroencephalography was firmly established in this country as a clinical and experimental technique, and much of the subsequent knowledge of the Berger phenomenon has originated in the United States.

Berger's discovery has become a cornerstone in the slowly growing structure of neurologic and psychiatric knowledge and affords a new basis for the dynamic approach to the study of brain function.

## MEDICAL EPONYM

### JACKSON'S MEMBRANE

Jabez N. Jackson (1868-1935), of Kansas City, Missouri, read a paper before the Western Surgical Society at Minneapolis, Minnesota, in December, 1908, entitled "Membranous Pericolitis." This was printed with revisions and additions in *Surgery, Gynecology and Obstetrics* (9: 278-287, 1909).

Wherever . . . we find any late manifestations of peritoneal disturbance about the colon we have been content to label it "adhesions," presume an antecedent acute appendicitis, and pass on. Some very striking . . . observations . . . have persuaded [the writer] that there is a most interesting pathological condition occurring about the right colon which can not thus readily be set aside. . . . The following description . . . is . . . from the report of Dr. Frank Hall, pathologist. . . . "From a point just at the hepatic flexure to three inches above the caput there spreads from the parietal margin over the external lateral margin to the internal longitudinal muscle band a thin vascular veil."

Synchronously with our recognition of the distinct pathology and clinical identity of this condition, we had been impressed with the view that this pericolonial membrane by its mechanical interference with colonic peristalsis was possibly, if not probably, responsible for the chain of symptoms which were manifest when it was found present.

### SECTION OF OBSTETRICS AND GYNECOLOGY\*

#### ATTEMPTED FORCEPS DELIVERY AND CESAREAN SECTION, FOLLOWED BY DEATH

A forty-year-old para IV entered the hospital at term, after being in labor for twenty-four hours at home. She was under ether when admitted.

The prenatal care during this pregnancy had been inadequate. The past history was irrelevant. The three previous pregnancies had terminated in normal deliveries, none of the babies weighing more than 6 pounds.

Prior to admission, the patient's family physician had unsuccessfully attempted forceps delivery, and the patient arrived at the hospital with the cord prolapsed. According to the admission note, the cervix was dilated to admit two fingers, the head was high, and a nonpulsating cord presented. The pulse rate was not recorded. A classic cesarean section was immediately performed, and an 8-pound, 5-ounce, stillborn baby was delivered. A drain was placed in the pelvis. During the first two weeks of convalescence, there was some febrile reaction, but no evidence of a generalized peritonitis. On the fourteenth day, the wound broke down, and evisceration of the bowels occurred. The bowels were replaced, the wound was resutured, and the patient was transfused. She died nineteen days after operation, the death certificate stating that she died of bronchopneumonia.

*Comment.* From beginning to end, this case represents poor obstetrics. The apparent size of the child, particularly in view of the fact that the three other babies were small, and the height of the head should have stimulated inquiry and possibly x-ray study. This patient undoubtedly had some form of contracted pelvis. When she entered the hospital, the cervix was said to have been only slightly dilated. This probably meant that the cervix had shut down after the attempt at delivery had failed, because it is not imaginable that anyone would attempt forceps delivery with such a dilatation of the cervix.

There were two ways of treating this patient after she arrived in the hospital with the cord prolapsed, the baby dead and the uterus probably infected. One would have been an extraperitoneal section of the Waters type, accompanied by transfusion. If this had seemed to be contraindicated, cesarean section with hysterectomy would have been the operation of choice. This is a death resulting from intraperitoneal cesarean section, which was contraindicated from the outset.

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section. Letters should be addressed to Dr. Raymond S. Titus, Secretary, 330 Dartmouth Street, Boston.

## THERAPEUTIC CONSIDERATIONS OF THROMBOPHLEBITIS AND PHLEBOTHROMBOSIS\*

ALTON OCISNER, M.D.,† AND MICHAEL DEBAKEY, M.D.‡

NEW ORLEANS, LOUISIANA

AS emphasized in previous publications<sup>1-4</sup> from etiologic, prognostic and therapeutic stand points, it is important in intravenous thrombosis to distinguish between two major types of intravascular clotting, that is, thrombophlebitis and phlebothrombosis. The clotting in thrombophlebitis is the result of injury to the vascular endothelium from mechanical trauma, bacterial invasion or chemical injury, whereas in phlebothrombosis the intravascular thrombus formation is due to venous stasis and to alterations in the cellular and fluid constituents of the blood that increase the clotting tendency. The prognostic significance of this differentiation lies in the fact that in thrombophlebitis the clot is usually firmly adherent to the vein wall and is therefore less likely to be come detached and result in embolism. On the other hand, in phlebothrombosis the coagulum is loosely attached to the vessel and is therefore likely to cause embolism. The therapeutic significance of this differentiation lies in the recognition of the respective processes and the institution of appropriate measures to prevent the occurrence of complications and to enhance restitution.

In this presentation, no attempt is made to discuss etiology and pathogenesis because these have been reviewed in previous publications<sup>1-4</sup> and will be presented more extensively in subsequent reports.

### PROPHYLACTIC MEASURES

#### *Preoperative Procedures*

*Re establishment of normal cardiovascular function.* The possibility of intravenous clotting must be considered in any patient who has tissue injury as a result of operative, accidental or puerperal

trauma, and invasion by infection or neoplastic disease. Whereas preventive measures cannot be considered in many of these conditions, much can be accomplished prophylactically in the surgical and puerperal cases. Because cardiovascular disease, with its resultant circulatory retardation, may be a precipitating factor, it is essential to re-establish the *normal cardiovascular function* as much as possible before any operative procedure. Welch,<sup>5</sup> in 1900, reported 4 cases of thrombosis or thrombophlebitis of the upper extremity and collected 23 from the literature. At that time, he regarded this as a rare complication of heart disease. Belt<sup>6</sup> obtained a history of cardiac impairment in 49 of 56 cases of pulmonary embolism. He is of the opinion that circulatory embarrassment is of primary importance in the etiology of venous thrombosis and pulmonary embolism. Cardiovascular disease was the predominant illness in half the nonsurgical cases of pulmonary embolism studied by Henderson.<sup>7</sup> Ophuls and Dobson<sup>8</sup> found cardiovascular disease in 52 per cent of their cases of thrombosis and embolism. Putnoky and Farkas<sup>9</sup> noted that approximately 90 per cent of 91 cases of pulmonary embolism had cardiovascular disease, and a large number of these showed fatty degeneration of the myocardium. Bauer<sup>10</sup> found that the patients in 95 of 100 cases of postoperative thrombosis and embolism had abnormal hearts. He is of the opinion that impairment of cardiac function is an important factor in the etiology of venous thrombosis. Oberndorfer<sup>11</sup> observed that of 97 fatal medical cases of pulmonary embolism, 64 patients had cardiovascular disease at the time of the terminal seizure. Rosenthal<sup>12</sup> reported 94 cases of thrombosis in 149 autopsies performed on patients with cardiac decompensation. Aukhausen<sup>13</sup> reported 270 cases of venous thrombosis in 1472 autopsies on patients with heart disease. Storz<sup>14</sup> emphasizes that the incidence of thrombosis is dependent more on the condition of the heart and

\*The Shattuck Lecture delivered at the annual meeting of the Massachusetts Medical Society, Boston, May 21, 1941.

†From the Department of Surgery, Tulane University of Louisiana School of Medicine.

Assistant professor of surgery, Tulane University of Louisiana School of Medicine, visiting surgeon, Charity Hospital.

the circulatory system than it is on the disease process or the operation. Kuhn<sup>15</sup> found that in autopsy material, between the years 1919 and 1927, — during which there was a definite increase in vascular diseases, particularly arteriosclerosis, — there was a marked increase in thrombosis. Burke<sup>16</sup> reported that of a total of 648 cases of intravascular clotting, 444 were associated with cardiac disease. His statistics further emphasize the importance of cardiovascular disease in the development of thrombosis, because in this series there were 218 patients who developed thromboses after escaping it following a previous operation. Of this number, 179 had cardiovascular disease as a primary or an important secondary condition. Barker and his co-workers<sup>17</sup> found that of 1665 patients with thrombosis and embolism, 219 (13.1 per cent) had cardiac disease.

Of great significance from the standpoint of cardiovascular disturbance is advancing age. It is well known that in older persons, because of the decrease in cardiovascular activity, thromboses are likelier to occur. According to Ewald,<sup>18</sup> intravenous clotting occurs in young people only when there is a circulatory disturbance. Koch<sup>19</sup> found that between the ages of fifteen and nineteen years the circulation time averaged eighteen seconds; between thirty and forty years it was twenty-one seconds, and at seventy years it was twenty-three seconds. In patients in whom there was a circulatory disturbance, the circulation time was frequently as much as sixty-one seconds, and after operation there was a definite interference with the circulation. Numerous other observers have emphasized the effect of cardiovascular disease in the production of intravenous clotting and the necessity for treatment of cardiovascular dysfunction.<sup>20-27</sup> Blumgart and Weiss,<sup>28</sup> from clinical investigations concerning circulation time, found that in general the degree of cardiac decompensation is of importance. These clinical observations emphasize the significance of cardiovascular diseases in the production of intravenous thrombosis and indicate the necessity of their detection and correction preoperatively. The value of prophylaxis in this connection is exemplified by von Jaschke's<sup>22</sup> results. Whereas in a series of 2053 operations the incidences of thrombosis and fatal embolism were 1.75 and 0.6 per cent respectively, in a comparable series of 1362 operations in which the patients were systematically digitalized preoperatively, the corresponding incidences of thrombosis and fatal embolism were 0.9 and 0.5 per cent. Koenig<sup>29</sup> found that, following the use of Sympathol in 2000 cases postoperatively, the incidence of thrombosis and embolism decreased from 6.2 to 0.95 per cent. Similarly, Frau-

endorfer<sup>30</sup> observed a decrease from 10.6 to 2.3 per cent and in the mortality from 2.3 to 0 per cent. Similar observations have been made by others.<sup>31, 32</sup>

Because of the definite vasoconstrictor effect of *smoking*, it is essential preoperatively, particularly before an operation in which there is likely to be considerable trauma, that smoking be stopped for a period of days or weeks. As has been emphasized in previous publications, smoking produces distinct vasospasm and thus favors vascular retardation, which in turn is an important factor in the production of intravenous clotting. Subsequently, when the treatment of intravascular clotting by vasodilatation is discussed, the role of vasospasm in the production of the condition will be emphasized.

In *varicosities* of the lower extremity with associated venous stasis,<sup>33</sup> the possibility of thromboses in the dilated veins must be considered. Barker et al.<sup>17</sup> found that of 1665 cases of thrombosis and embolism, 203 had simple varicosities of the lower extremity. The importance of varicosities as a factor in thrombophlebitis has been repeatedly emphasized.<sup>18, 21, 34-39</sup> For this reason, varicosities must be corrected preoperatively either by curative measures or by palliative compression with bandages, which should be worn during the early postoperative period. By so compressing and obliterating the dilated, superficial venous system, stagnation of blood in the superficial system is obviated and the rate of blood flow in the deep venous system is increased, both of which tend to decrease retardation. In this way the possibility of thromboses both in the superficial and deep veins is diminished.

The value of compression of the superficial veins in thrombophlebitis was first stressed by Fischer.<sup>40</sup> A great deal can be accomplished prophylactically by the use of compression bandages even in patients who have no varicosities, because by compressing the superficial veins the rate of flow in the deep veins is increased. Numerous observers have directed attention to the prophylactic value of compression,<sup>21, 26, 36, 37, 41-44</sup> particularly in the presence of *predisposition* to thrombophlebitis or phlebothrombosis. Leunt<sup>45</sup> states that for nine years he and his associates have been using compression bandages prophylactically in patients in whom they feared a thrombosis — these are patients who had varicosities, circulatory disturbances or other *predisposing factors*. In 280 cases, they applied five hundred elastic compression bandages. In 3 cases, the treatment was a failure in that a thrombosis occurred. In two of these, slight thrombosis occurred because the bandage was not applied tightly enough, and the third

patient died of a pulmonary embolism, but autopsy showed that the thrombus originated from a pelvic vein and not from a leg vein. Although Unna<sup>46</sup> and Lasker<sup>46</sup> have suggested the use of Unna's paste boot for its antiphlogistic action, most observers agree that the compression is the significant factor, and it is for this reason that an adhesive elastic bandage is usually preferred to a simple adhesive plaster.

As we<sup>1-4</sup> have previously stated, constitutional predisposition is a definite familial tendency.<sup>47-58</sup> These patients characteristically are fat, weak-muscled and pale skinned, and have a relatively low blood pressure, vagotonia and a psychic lability.

*Reduction in weight.* Numerous observers have directed attention to obesity as a predisposing factor in thrombosis.<sup>18, 41, 42, 59, 60</sup> Snell<sup>60</sup> found that of 150 obese patients who died postoperatively the cause of death was thromboembolism in 48 (31 per cent). Henderson,<sup>7</sup> in a statistical analysis of post-mortem thromboembolism cases, reported that the average weight of the patients was 13 pounds greater than normal. Barker and his co-workers<sup>17</sup> reported that obesity exerts a definite influence on the production of thrombosis and embolism. They observed that in patients who had an abdominal hysterectomy the incidence of postoperative venous thrombosis and pulmonary embolism was 4 per cent in patients who weighed less than 200 pounds and 8 per cent in those weighing more than 200 pounds. Of 3680 patients on whom intestinal operations were done, thromboembolism occurred in 3.2 per cent of those who weighed less than 200 pounds, and 7.1 per cent of those who weighed more than 200 pounds. Friedländer<sup>41, 42</sup> believes that in obese patients interference with the return flow of blood through the femoral veins is greater because the opening in the femoral canal is encroached upon by fat and because the fat bolster in the buttock is larger and thus results in greater elevation of the pelvis. This makes a higher angle in the femoral vein and thus further interferes with the flow of blood into the pelvis. According to Snell,<sup>60</sup> the increased incidence of thrombosis in obese persons is due to the greater difficulty in operating, to the greater likelihood of circulatory retardation and to the liberation of large quantities of lipid thromboplastic substances. Rösse<sup>61</sup> is of the opinion that in obese persons, because of the increased weight of the leg, the pressure of the calf muscles against the bed is sufficient to compress the veins, and thus predisposes to intravascular clotting. These observations emphasize the importance of obesity in the production of thromboembolism and indi-

cate the necessity of reduction in weight as a preoperative prophylactic measure.

*Elimination of foci of infection.* As emphasized in previous publications,<sup>1-4</sup> infections are contributory in the production of distant thromboses, because of the changes in the blood constituents resulting from destruction of tissue. For this reason, it is prophylactically desirable to remove all foci of infection whenever possible. Gougerot and Frumusan<sup>62</sup> reported a case of phlebitis studied bacteriologically and histologically in which an anaerobic streptococcus was found in an abscessed tooth, the intradermal reactions to this organism being strongly positive. Biopsy of the phlebotic vein showed the same organism. Of interest in this connection is the report of a case of migratory thrombophlebitis which was apparently due to a focus of infection in a tooth, since recovery followed its extraction.<sup>63</sup> The relative frequency of thrombophlebitis complicating typhoid fever has long been known. It has been recently emphasized by Conner,<sup>64</sup> who states that this incidence is as high as 10 per cent. It has also been recognized as a complication of Boutonneuse fever.<sup>65</sup> Barker and his co-workers<sup>17</sup> found that of 1665 cases of thromboembolism there were 379 (22.8 per cent) with severe infections. Other infections that are likely to be associated with thrombosis are influenza, acute rheumatic fever, syphilis and endocarditis. Bargen and Barker<sup>66</sup> have stressed the importance of thrombosis as a complication of chronic ulcerative colitis; they observed 18 cases with severe thromboses among 1500 cases of the disease.

*Significance of cancer.* The significance of malignant neoplasms as predisposing factors has also been emphasized. Trousseau<sup>67</sup> was one of the first to call attention to the causal relation of cancer and thrombosis and to note that frequently the first manifestation of an internal cancer is peripheral phlebitis. Sproul<sup>68</sup> noted the relatively high incidence of venous thrombosis as a complication of carcinomas of the body or the tail of the pancreas. In 56 per cent of cases of carcinoma of these portions of the pancreas, a single thrombus was present, whereas in 31 per cent the venous thrombosis was largely disseminated. Flörcken<sup>21</sup> and Schäfer<sup>69</sup> have also emphasized the effect of carcinoma as an etiologic factor. In patients with cancer, because of the tendency toward thrombosis, it is essential to use prophylactic measures. In the absence of specific preventive measures, compression of the extremities by means of elastic adhesive is of great value.

*Hydration and mineralization.* The replacement of fluid as a preoperative measure is imperative

because dehydration and increased viscosity of blood predispose to thrombosis. As emphasized by Gordon-Watson,<sup>70</sup> it is essential to replenish the fluids in those patients who have had purgation preoperatively and who have lost considerable fluid by hemorrhage, sweating or vomiting. Preoperative remineralization is of equal value. Kopf<sup>71</sup> is of the opinion that the highly purified sodium chloride employed at present is responsible for the high incidence of thrombosis. He believes that a great deal can be accomplished in the preparation of these patients by giving various salts beforehand, such as mineral water, Brunner's salts and Glauber's salts. Ross<sup>72</sup> found in experimental animals that following the administration of small amounts of calcium nitrate there was an increased tendency to thrombosis because of the alteration in the calcium-sodium ratio. Russo<sup>73</sup> attempted to determine whether there is a sodium chloride deficiency in thrombosis. He investigated 44 cases either at the time of or shortly after the occurrence of a venous thrombosis. Of these, 8 patients had thrombosis of both lower extremities; 10, pulmonary infarction; 21, marked cardiac insufficiency; and 2, postpartum thrombosis. The sodium chloride values of the blood serum in 10 cases fluctuated between 500 and 550 mg.; in 28, between 550 and 600 mg.; and in 6, between 600 and 620 mg. per 100 cc. On the basis of these results, Russo concludes that hypochloremia is not a factor in the production of thrombosis. These conclusions are supported by the contentions of Vogt,<sup>26</sup> who believes that a salt-free diet is of prophylactic value. On the other hand, Menninger-Lerchenthal<sup>74</sup> is of the opinion that a hypochloremia is a factor in thrombosis. He reports 5 cases of spontaneous thrombosis or thrombophlebitis in patients who received varying doses of sodium bromide and who were on a low-salt diet. He thinks that the administration of bromides results in displacement of the chloride radicle, which according to him and to Prima<sup>75</sup> exerts a detoxifying action. These authors are of the opinion that postoperative hypochloremia is a factor in the development of thrombosis. Prima has given 400 to 1000 cc. of physiologic saline solution to all patients postoperatively, and during a period of thirteen years has never seen any thrombosis. It is evident that hydration and remineralization are useful measures in the prevention of thromboembolism.

*Correction of anemia and other dyscrasias.* It is essential preoperatively to correct an existing anemia, because of the increased tendency to thrombosis in such a condition. Lockhart-Mummery<sup>76</sup> and Donald,<sup>77</sup> in 1924, directed attention to the

greater likelihood of thrombosis in anemia. The latter reported 3 cases of profound anemia in which the patients developed fatal pulmonary embolisms, and believed that the thrombosis was to a large extent caused by the anemia. Others<sup>78, 79</sup> have also emphasized the increased incidence of thrombosis in patients with long-continued hemorrhage. Drinker, Drinker and Kreutzmann<sup>80</sup> demonstrated that following hemorrhage there is an increase in the cellular elements, which may increase the coagulability of the blood. These changes may be at least partly responsible for the increased incidence of intravenous clotting in cases of anemia secondary to hemorrhage. In addition to the increased coagulability of blood, anemia also predisposes to thrombosis because of its secondary effect on the cardiovascular system, resulting in diminution in cardiac tone, and circulatory retardation. Because anemia is an important predisposing factor in thromboembolism, careful blood studies must be made preoperatively in all cases, and deficiencies should be corrected by blood transfusions and other appropriate measures. Polycythemia is not infrequently complicated by intravascular clotting, particularly in the portal vein, probably because of the increased viscosity of the blood resulting from the increased number of erythrocytes. In such cases, it is desirable to employ venesection preoperatively.

Whereas intravenous clotting can occur in any patient, it is particularly likely to occur in the presence of the predisposing factors discussed above. Accordingly, it is essential that such factors be recognized preoperatively, that appropriate prophylactic measures may be instituted. Obviously, in some cases, the prophylactic measures that can be used are specific, such as correction of cardiovascular disturbances, whereas in others the preventive measures are necessarily nonspecific.

### *Operative Procedures*

*Atraumatic surgery.* As emphasized previously,<sup>1-4</sup> and as mentioned above, the absorption into the vascular system of proteid disintegration products originating from injured tissue, as a result of operative, accidental or puerperal trauma, infection and invasion by cancer, increases the coagulability of the blood and predisposes to intravascular clotting. The role of accidental trauma is emphasized by McCartney's<sup>81</sup> statistics. In 73 cases of pulmonary embolism there were 15 which were strictly post-traumatic; in 12 of the latter the patients had fractures of the lower extremity, and in all, the patients were confined to bed. Potts<sup>82</sup> reported 95 cases with fractures of the lower extremity, in 5 of which the patients

developed thrombophlebitis; he is of the opinion that thrombophlebitis developed in these cases partly because the extremity was immobilized and the patient was unable to take exercises.

Whereas it is impossible to control the degree of accidental trauma and difficult, if at all possible, to control the injury to tissue by infection and neoplastic disease, a great deal can be accomplished operatively by employing atraumatic surgery. As has been repeatedly stressed, *sharp dissection* results in less trauma than blunt dissection. The *gentle handling of tissues* cannot be overemphasized. The clamping of vessels only and the avoidance of mass grasping of tissue are essential. The significance of operative trauma in the production of postoperative thrombosis has been emphasized by a number of clinical and experimental observations.<sup>24, 29, 70, 76, 78, 83-85</sup> Lambret and Driesens<sup>80</sup> found that following an operation there was a rise in the polypeptides, which reached its maximum about the fifth day, and that this was more prolonged the more traumatic and the more histolytic the operative procedure. Mason<sup>81</sup> and Takaura<sup>82</sup> have shown that tissue extracts are potent in the production of intravascular clotting, the former investigator having found that 0.003 gm. of lung-tissue extract will produce complete intravascular coagulation in a rabbit. Of equal importance is the *absolute hemostasis*, because the absorption of blood from a wound gives rise to proteid disintegration products. Because absorbable suture material produces an intense inflammatory reaction, which is necessary for proteolytic digestion of the suture, greater tissue injury occurs in wounds closed with such material, a condition that increases the absorption of split-protein products. If *fine nonabsorbable suture material* is used, this reaction of the wound is definitely decreased, as evidenced by the clinical appearance of the wound and by a much lower temperature curve. This is further supported by the histologic examination of experimentally produced wounds.<sup>93</sup> In our clinic, we have for the past two years used cotton suture material exclusively, because it was found experimentally that this material gave the least reaction of all those investigated.

**Avoidance of contamination.** It is imperative that the trauma during the operation be reduced to a minimum, and that contamination of the wound be prevented, not only because the infection itself is undesirable, but also because of its effect on intravascular clotting. The continuation of the infection with the destruction of tissue, causing the liberation of larger quantities of split proteins, favors thrombosis.

**Hydration and mineralization.** During the op-

erative procedure, it is essential that excessive loss of fluid be prevented. Commonly, under a general anesthetic, there is considerable loss of fluid through perspiration and insensibly through the lungs. Because dehydration and loss of electrolytes predispose to thrombosis, fluids should be administered parenterally, either intravenously or subcutaneously, during the operation. The importance of the fluid loss during an operative procedure has repeatedly been emphasized by Collier and his associates.<sup>94, 95</sup>

**Prevention of circulatory collapse.** Patients who are submitted to extensive operative procedures with considerable trauma, particularly if there is much loss of blood, may develop a circulatory collapse. In such cases, it is imperative to prevent this collapse by the prophylactic administration of saline solution, blood or plasma. It may be necessary to resort to vasoconstrictor drugs, to prevent the prolongation of a hypotension, which would predispose to intravascular clotting. The prevention of circulatory collapse, owing to its effect on intravascular clotting, is of value because such collapse favors vascular retardation, anoxia and injury to the vascular endothelium and, if prolonged, increases the blood viscosity.<sup>96</sup>

**Avoidance of chilling.** Chilling during and after the operation should be prevented because of its vasoconstrictor effect, which predisposes to vascular retardation. Chilling is probably detrimental in another way, since it increases the viscosity of the blood, as shown by Barbour and Hamilton,<sup>97</sup> who demonstrated that exposure to cold causes a loss of fluid from the vascular channels into the tissues. This increases the viscosity and the clotting tendency, and is probably the effect of a combined sympatoadrenal activity. The necessity of preventing chilling during the operative procedure has been emphasized by Leriche<sup>98</sup> and others,<sup>99, 100</sup> who employed infrared irradiation during the course of an operation. Birgus<sup>101</sup> suggested the use of flannel stockings during the operative procedure to prevent chilling. This is an extremely valuable suggestion, and stockings should be applied to the lower extremities during not only the operation but also the postoperative period.

#### Postoperative Procedures

**Hydration and mineralization.** After a patient has been returned to his bed following an operative procedure, it is imperative that the replacement of fluids and electrolytes be continued, because in the early postoperative period, particularly after laparotomy, the patient is unable to take fluids by mouth and frequently is losing considerable fluid from his stomach and intestine as

a result of vomiting or removal by means of an indwelling duodenal catheter. An increased viscosity of the blood may occur postoperatively, as demonstrated by Zarubin<sup>102</sup> and Bolognesi.<sup>103</sup> Similar observations were made by Löhr and Löhr,<sup>104</sup> who found that the viscosity parallels the erythrocytic sedimentation rate. In addition to the reasons mentioned above for the administration of fluids and electrolytes, it is essential that the water balance be re-established as quickly as possible, because in this way the elimination of waste products, among which are the split-protein substances that predispose to intravascular clotting, is effected.

**Posture.** The posture of the patient postoperatively is of great importance in predisposing to or preventing thrombosis. Because vascular retardation is a prominent precipitating factor in the production of intravascular clotting, postures that cause slowing of the blood stream should be avoided, and conversely, postures that favor the return flow of blood in the venous system should be used. The placing of a patient in a Fowler's position, with flexion of the thighs on the abdomen and flexion of the legs on the thighs at the knees, results in compression of the vessels in the popliteal space and should therefore be avoided. Whereas flexion of the thigh on the trunk theoretically produces compression of the femoroiliac veins beneath the inguinal ligament, Friedländer<sup>42</sup> has shown that such a position actually produces less compression, favors the return flow of blood, and tends to prevent vascular retardation. This may be accomplished either by elevating the foot of the bed from 30 to 45 cm. or, preferably, by elevation of the leg and foot and flexion of the thigh on the trunk at an angle of 45°. Friedländer showed that, if the thigh is extended and on a level with the trunk, the femoroiliac veins are kinked as they pass from the thigh through the inguinal canals down into the pelvis, and that the veins assume a straight direction if the thigh is flexed on the trunk at an angle of 45°. He also emphasizes the value of elevating the leg above the level of the thigh so that no kinking occurs in the popliteal space. Elevation of the foot of the bed to prevent vascular retardation, a procedure that we believe should be employed, has been repeatedly emphasized.<sup>18, 22, 42, 101, 105-113</sup> Frykholm<sup>114, 115</sup> and Patey<sup>116</sup> advocate elevation of the head of the bed as a prophylactic measure in intravascular clotting. Frykholm is of the opinion that if the lower extremities are elevated, the deep veins become emptied of their blood and the venous endothelium suffers, because lack of nutrition causes changes that favor thrombosis. On

the other hand, if the patient is placed in a head-up position, these veins become filled, the vascular endothelium is better nourished, and there is less danger of change in the endothelium and resultant thrombosis. Patey believes that the contraction of the muscles necessary to keep the patient in this position favors the movement of blood, a factor that cannot be denied, and that if thrombosis does occur, it will take place in a vessel that is dilated and in which a greater inflammatory reaction and a more extensive clot will result, tending to fix the thrombus in the vessel. Whereas muscular contractions are necessary to keep the patient in the head-up position and are of undoubted benefit, it is our firm conviction that better results are obtained by elevation and mobilization of the extremities, which speed up the blood flow and prevent circulatory retardation.

**Mobilization.** The immobility of a patient postoperatively is undesirable for several reasons. As a result of the quiescence, cardiovascular activity is decreased, which tends to produce vascular retardation. Muscular inactivity predisposes to vascular stasis because the movement of blood in the vein is dependent to a great extent on the contraction of muscles. For these reasons, early postoperative mobilization is essential as a prophylactic measure in venous thrombosis. Ries,<sup>117</sup> Richardson,<sup>118</sup> Boldt<sup>119</sup> and others<sup>120-125</sup> were early advocates of movement of the legs while the patient is in bed. More recently, the significance of such exercise has been further emphasized.<sup>1-4, 27, 78, 82, 105, 126-136</sup> Although the bed bicycle of Gamble<sup>137</sup> and the elaborate mass gymnastic procedures recommended by Kirschner,<sup>138</sup> which consist in performing co-ordinated exercises twice daily with music under the supervision of a gymnast, are probably unnecessary, movement of the muscles of the lower extremities, preferably against a resistance, should be used in all cases when possible. Potts<sup>82</sup> has emphasized that whereas thrombosis and embolism are common in patients with fractures who are confined to bed and in plaster encasements, they are rare in ambulatory patients with arm, leg, shoulder or spine fractures, in similar encasement. In each case, the amount of tissue trauma and the local immobility are the same, the only difference being the systemic immobility in the former and the systemic mobility in the latter. The value of local and systemic immobilization is further stressed by McCartney's<sup>81</sup> 73 cases of pulmonary embolism, of which 15 were strictly post-traumatic; 12 of these patients had lower-extremity fractures and were confined to bed. That exercises alone will not prevent intravascular clotting, however, is exemplified by a case of Conner's in which

rather extensive thrombosis occurred in a patient with typhoid fever who conscientiously used daily exercises of his arms and legs.

*Early ambulation.* Early ambulation of the patient postoperatively is favored in most Continental clinics. Not infrequently, a patient who has had an appendectomy performed through a muscle-splitting incision under local analgesia is permitted to walk back to his room. Campeanu<sup>139</sup> reported 1300 cases, many of which were severe, in which the patients were allowed to walk directly from the operating room to the ward and to take gymnastic exercises immediately afterward, including even jumping. Campeanu has extended early ambulation to such an enthusiastically ludicrous degree that he performed an appendectomy on one of his assistants, who immediately afterward assisted him in another operation, and also on another assistant, who immediately afterward performed an appendectomy. Patients who have had extensive operations, such as resection of the stomach, are allowed to sit on the edge of the bed on the afternoon of the operation, and to sit out of the bed the day following the operation. This ambulation is used for two reasons: to decrease the circulatory retardation, and to diminish the incidence of respiratory infection. Zava<sup>140</sup> quotes his experience with this therapy in more than 6000 operations without a single case of embolism, although many of the cases were gynecologic or other pelvic procedures. He gets his patients up either on the first or second day, and, if this is not possible, he keeps them in bed until the second week, because he quotes Forgue as stating that embolism is likeliest to occur between the third and thirteenth days. The value of early ambulation is emphasized by von Jaschke,<sup>22</sup> who found that among 300 cases in which patients were allowed to get up relatively late, there were 2 per cent thromboses and 1 per cent fatal emboli, whereas in 387 cases in which early ambulation was used, the incidence of thromboses was 0.5 per cent and there were no fatal emboli. In the Essinger University Clinic, there were, from 1906 to 1912, operations on 1504 cases, following which the patients got up at the end of the second week and in which the incidences of thrombosis and fatal embolism were 2.63 and 1.40 per cent, respectively. From 1912 to 1918, there were operations on 2053 cases, following which patients got out of bed between the second and fifth days and in which the corresponding incidences were 1.75 and 0.6 per cent. Smith<sup>141</sup> reports abdominal or pelvic operations following which the patients have got out of bed within a few days. There were four deaths in the group, one of which

was due to embolism; none of the cases could be attributed to the early rising. Voegt<sup>135</sup> and von Jaschke<sup>22</sup> are other advocates of early ambulation. The advantage of getting the patient out of bed relatively early is exemplified by the investigations of Smith and Allen,<sup>142</sup> in which it was shown that postoperatively beginning on the fifth day the circulation time was increased and that on the tenth day it was approximately 50 per cent greater than the preoperative average. Eighty-two per cent of the individual cases showed increases of four or more seconds at some time after the operation. Similar observations were made by Sylvan.<sup>32</sup>

*Respiratory stimulation.* Normally, the negative pressure within the thorax favors the return of venous blood to the cardiac chambers. Because of the diminished respiratory activity that follows operation, there is an interference with the normal venous return. Moreover, hypopnea occurs postoperatively as a result of pain caused by movement of the abdominal muscles and an increase in abdominal tension. It has been shown repeatedly that postoperatively the diaphragmatic excursions are diminished, which results in concomitant diminution in the negative intrapleural pressure, venous stasis and circulatory retardation.<sup>143-152</sup> Prevention of hypopnea is therefore important, and patients should be instructed to take frequent deep breaths during their waking hours. It is the custom in our clinic to have the patient take at least ten deep breaths every hour. Whereas it is frequently necessary to insist on voluntary deep breathing, which is preferable, if this is not possible it may be necessary to employ carbon dioxide inhalations.<sup>153 157 158</sup> Because of the depressant effect of opiates on the respiratory center, it is desirable to use them as sparingly as possible, to minimize the danger of hypopnea. The value of deep breathing has been repeatedly emphasized.<sup>19 20 78 82 93 101 105 116 122 123 131 134 135 154 155</sup>

*Abdominal tension.* Increased intra-abdominal pressure also favors circulatory retardation by exerting pressure on the intra-abdominal veins, and thus interfering with the return flow of venous blood from the lower extremities. Increased intra-abdominal tension may result from a number of factors, such as application of constricting bandages, which are frequently used by surgeons in an attempt to give support to the abdominal wall, and functional inactivity of the gastrointestinal tract, with its associated accumulation of fluid and gas in the stomach and the intestine (ileus). For this reason, the increased intra-abdominal tension resulting from tight bandages or from ileus should

be combated by avoidance of tight dressings, by the use of appropriate devices, such as the indwelling catheter and the double tube, and by other methods previously described.<sup>156</sup> As shown by Pat-ey<sup>116, 161</sup> and Frimann-Dahl,<sup>147</sup> there is a definite increased intra-abdominal tension postoperatively, apparently the result of a decreased action of the diaphragm and the splinting of the abdominal wall.

*Compression bandages.* In patients in whom an intravenous clotting is likely to occur the application of compression bandages to both lower extremities should be used postoperatively for the same reasons advocated for their preoperative use, given above.

*Heat.* The application of heat in the form of a heat tent to the lower part of the abdomen and the extremities is undoubtedly of value after an operation, not only because of its beneficial effect on the tone of the intestine, but also because it produces reflex vasodilatation of the peripheral vessels. The extremely low incidence of intravascular clotting in our clinic is owing, we believe, to the fact that large heat tents covering the abdomen and lower extremities are routinely used postoperatively. The application of heat is particularly important, because circulatory activity is further decreased by the peripheral vasoconstriction that has been shown to exist by Leriche<sup>98</sup> and Kvale,<sup>157</sup> and in previous investigations by us. Because of the vasoconstriction of the capillary bed, venous stasis occurs, which in turn predisposes to thrombosis. Smith and Allen<sup>142</sup> showed that postoperatively the circulation was definitely slowed and that this was more pronounced when the extremity was cold and less marked when it was hot, irrespective of the cause of vasodilatation. The use of woolen or flannel stockings postoperatively, to retain the body heat and prevent irradiation, cooling and vasoconstriction, is desirable.

*Hirudinization and heparinization.* The use of anticoagulants as prophylactic measures has become increasingly popular. Hirudinization and heparinization owe their efficacy to their anticoagulant activity. The former has been emphasized by one of us in collaboration with Mahorner,<sup>158</sup> and more recently by Chalié,<sup>159</sup> and Rouhier.<sup>160</sup> Murray and Best and their co-workers<sup>161-163</sup> in Canada, Crafoord<sup>164, 165</sup> in Sweden, and Priestley, Essex and Barker<sup>166</sup> in this country have used heparin prophylactically to prevent thromboembolic phenomena. These investigators found experimentally that by administering purified heparin intravenously over a period of hours it was possible to diminish the coagulation time considerably. Good results have been reported from its clinical use. Murray and Best<sup>161-163</sup> used

heparin postoperatively in 315 cases, and in none did thromboembolism develop. Crafoord<sup>164, 165</sup> treated 126 cases prophylactically with heparin one developed a pyrexia, which might have been due to thrombosis. In a control group of 80 cases, 122 patients (15 per cent) had evidence of thromboembolism, although in 64 of these the only manifestations of thrombosis were changes in temperature and pulse. Sodium citrate intravenously has been suggested by Kreiner<sup>167</sup> and others<sup>12</sup> as another prophylactic anticoagulant. Unless there is definite evidence of hereditary predisposition or unless the patient gives a history of having had previous thromboses, it is doubtful whether the routine use of any of these anticoagulants is justified prophylactically.

#### THERAPEUTIC MEASURES

By the institution of the above prophylactic measures, most cases of intravascular clotting can be prevented, and this without doubt is a desideratum. Occasionally, in spite of the use of these procedures, intravascular clotting occurs. The prognosis and the therapy in each case are dependent on the type of the lesion and its location. Of great significance is the differentiation between intravascular clotting in the superficial and in the deep veins, and of even greater importance is the distinction between intravascular coagulation associated with an inflammatory lesion of the vein, that is, thrombophlebitis, and coagulation in which there is no associated inflammatory process, that is, phlebothrombosis. Generally, the prognosis is better, and the therapy more easily applied in cases with superficial thrombosis than in those with thrombosis of the deep veins.

##### *Superficial Thrombosis*

*Thrombophlebitis.* In cases of thrombophlebitis involving the superficial veins, the treatment is usually *conservative* and consists in compression of the entire extremity from the metatarsal phalangeal joints up to the groin. Adhesive elastic bandages should be applied to the thigh because of the difficulty of preventing the ordinary type of compression bandage from slipping owing to the conical shape of the thigh. To prevent propagation of a thrombus, it is imperative that these patients be treated by ambulation and not be allowed to remain in bed. The value of the compression and ambulation therapy was first emphasized by Fischer.<sup>40</sup> Compression of the extremity is efficacious by compressing the vein wall against the thrombus, tending to fix it, and by producing relative immobility of the vein.

Whereas thrombophlebitis in the superficial veins can usually be treated satisfactorily by compression and ambulation, *radical therapy*—high

ligation—is occasionally desirable. In the majority of superficial thrombophlebitides, radical therapy is unnecessary; however, because of the occasional detachment of a superficial thrombus resulting in massive embolism, this procedure becomes lifesaving. We have observed 4 cases at autopsy in which death resulted from a massive pulmonary embolism, the clot originating in the long saphenous vein. These fatalities could have been prevented by the timely ligation of the saphenous at its junction with the femoral vein. Homans<sup>168</sup> states that he has observed infarction but never fatal pulmonary embolism following thrombophlebitis of varicosities. We believe that in cases with long-saphenous-vein involvement in which the thrombophlebitic process has extended up to the lower part of the thigh, it is desirable to do a high ligation at its junction with the femoral vein and to follow this by compression and ambulation. Approximately forty-five years ago, Gluck<sup>169</sup> reported a case of postpuerperal thrombophlebitis of the long saphenous vein successfully treated by proximal ligation. In 1909, Müller<sup>170</sup> reported a similar case. Homans<sup>168</sup> advocates high ligation of the long saphenous vein when it is involved in a thrombophlebitic process. Hollingsworth<sup>171</sup> has recently reported a case in which this was done. Occasionally in varicosities, particularly those involving the leg at the site of a hugely dilated vein, localized thrombophlebitis occurs. This is extremely painful and may result in an ulceration, owing to interference with the blood supply. In such cases, local excision of the thrombophlebitic segment is desirable. When suppuration occurs in the thrombophlebitic segment, high ligation of the saphenous should be performed because of the possible propagation of the thrombus and detachment of infected emboli. Occasionally, excision of a localized thrombophlebitic segment of vein is desirable when an intraluminal suppuration occurs. Generally, however, because the suppurative process extends beyond the vein, in addition to high ligation of the main stem of the superficial vein, incision and drainage of the involved areas are necessary. Büdinger<sup>172</sup> advocated multiple incisions along the course of the involved veins in suppurative superficial thrombophlebitis. Eisenklam, a student of Büdinger, recently reported the results in 66 cases of nonsuppurative and suppurative superficial thrombophlebitis. Forty-two patients so treated were discharged from the hospital on the seventh or eighth day. In one of our cases, incision and drainage of a local suppurative thrombophlebitic process resulted in prompt cure. In another with propagation and evidence of sepsis, high ligation was necessary and was followed by recovery. In

a third with a rapidly progressing suppurative thrombophlebitis and sepsis, as evidenced by positive blood cultures, high ligation and subsequent incisions and drainages were necessary to effect a cure.

**Phlebothrombosis.** Thrombophlebitis of the superficial veins can be readily recognized not only by the presence of the palpable clot in the vein but also by local manifestations of inflammatory reaction, namely, tenderness, redness and increased heat over the involved vein. On the other hand, intravascular clotting unassociated with an inflammatory reaction, phlebothrombosis, occurs with evidence of minimal inflammatory reaction, the principal manifestation being a palpable clot in the vein. As mentioned before, the danger of such a clot's becoming detached, and thus gaining entrance to the venous system and being carried to the pulmonary veins, is particularly great. It is for this reason that these patients should never be treated conservatively, but high ligation of the vein at its junction with the deep venous system should be done as early as possible, the extremity compressed by means of bandages, and the patient made ambulatory. This relatively simple procedure will not only shorten the patient's convalescence but will in many cases prevent tragic complications resulting from the detachment of the nonadherent clot.

#### *Deep Thrombosis*

Intravascular clotting of the deep veins produces a different clinical picture from that of the superficial veins, and here again one must distinguish between thrombophlebitis and phlebothrombosis.

**Thrombophlebitis.** In cases in which there is an inflammatory involvement of the vein with accompanying systemic manifestations of infection, such as fever and leukocytosis, there is generally a decrease in the surface temperature of the involved extremity, a paradoxical manifestation. This is in contrast to the thrombophlebitic lesions involving the superficial veins in which the skin overlying the vein is red and warm. It has been well known for years that the involved extremity of patients with deep thrombophlebitis, particularly in the femoroliac veins, in addition to being swollen, is white and frequently has a cyanotic hue as well as a decrease in the surface temperature. The significance of this paradoxical manifestation, that is, coldness and pallor in the area of involvement in the presence of inflammation and pyrexia, was not appreciated by us until it became apparent by our animal and clinical investigations that, although the lesion was primarily in the large, deep veins, the manifestations were principally those of spasm of the arterial system, the decrease in tem-

perature and the whiteness of the extremity being due to ischemia.

The treatment of thrombophlebitis of the deep veins can be divided into two large categories, *conservative therapy* and radical therapy. In most cases, the former suffices. Elevation of the extremity should be carried on because it favors the return flow of blood and tends to decrease the propagation of the thrombus. Whereas immobilization previously has been considered an important form of therapy,<sup>34, 87, 113, 126, 129, 131, 174-185</sup> we are of the opinion that absolute immobilization is undesirable. Of great value in conservative therapy is the application of compression bandages to the extremity. The bandages should extend from the toes to the inguinal region. The rationale for their use has been discussed above, but briefly depends on an increased flow of blood in deep veins. Of equal significance is the beneficial effect they exert in preventing edema, and in retaining heat and increasing the vascularity of the extremity by virtue of the fact that they encase it. Müller<sup>43</sup> advocates the use of compression bandages and getting the patient up as soon as possible. He reports 85 cases of deep thromboses treated in this way. Many of the patients had massive swelling; some had pulmonary infarcts and had been in bed for weeks. Usually, after ten to fourteen days all symptoms had disappeared. In none of these cases did small lung infarcts develop, but there were two fatal pulmonary emboli, which the author believes cannot be blamed on the use of the compression bandage. In contrast, 40 cases of thrombophlebitis were treated by elevation only. In this group there were 6 cases (15 per cent) of fatal pulmonary embolism. There were 3 additional cases of pulmonary infarction. Müller states that compression treatment has decreased the incidence of fatal embolism from 15 to 2.3 per cent. He believes that compression re-establishes the competence of the venous valves and favors the attachment of the thrombus to the vein wall. He also thinks that by improving the circulation it prevents the propagation of a thrombus, which because of lack of attachment may be easily broken off and result in embolism. This is the most dangerous feature of thrombophlebitis. In his experience, the use of the compression bandage decreased the convalescent time from six to eight weeks to eight to twelve days. Fischer<sup>40</sup> has used this method of therapy in several thousand cases, and has never observed fatal embolism. Krammer<sup>186</sup> and Friedländer<sup>41</sup> treated a series of 196 cases by compression bandage, with only 1 case of fatal pulmonary embolism, which they thought was due to incorrect bandaging. On the

other hand, in 308 cases treated by elevation there were 64 cases (16 per cent) with fatal emboli.

Bahls<sup>187</sup> states that since 1923 in the Kappis Clinic they have used compression bandages in cases of thrombosis and thrombophlebitis. Of 181 cases of thrombosis, they have lost 6 patients from emboli. Three of these would have died anyway. He states that if the bandage is applied at the earliest manifestation of thrombosis, fatal pulmonary embolism does not occur. In cases of thrombophlebitis, he advocates the application of adhesive bandage and ambulation. Lepler<sup>23</sup> treated 45 cases of postoperative thrombosis by means of adhesive plaster compression, and of this number 35 patients had no complications, 9 developed infarcts, and 1 died of pulmonary embolism. There were 36 cases with progressive thrombosis and thrombophlebitis treated in this way, in none of which complications occurred. In 17 cases of pulmonary infarction with no evidence of thrombosis, adhesive compression of the extremities was used prophylactically; of these, 3 patients developed fatal pulmonary emboli. Lepler<sup>23</sup> emphasizes that in the cases treated by adhesive compression in which ambulation was possible neither infarction nor fatal embolism developed, whereas infarction occurred in 9 and fatal pulmonary embolism in 4 patients who were bedridden in his series.

Cabernard<sup>188</sup> states that he used compression therapy in thrombosis and thrombophlebitis for five or six years in more than 100 cases and never observed infarcts or emboli. Whereas, previously, patients with thrombophlebitis had been kept in bed for six weeks, in this group they remained in bed only four or five days. Of about 40 cases with fever, 1 patient remained in bed for three weeks, 1 for fourteen days, and 2 for ten days. In the last 3 patients, the thrombophlebitis extended above the inguinal ligament. The other patients stayed in bed only two or three days. When the condition of the patient permitted, ambulation was begun on the day the bandage was applied. Numerous other observers are warm advocates of the use of compression bandages.<sup>18, 21, 26, 27, 36, 37, 113, 189-193</sup>

The application of heat postoperatively is of advantage in thrombophlebitis of the deep veins, as well as that in superficial veins. This has been adequately discussed above. Similarly, the use of anticoagulants, such as hirudin and heparin, may be of value in isolated cases. Termier,<sup>194</sup> in 1922, is credited with the revival of treatment of thrombophlebitis by leeches. He reported 73 cases in which this form of therapy was used with remarkable relief of acute manifestations. Subse-

quently, numerous others, especially in Europe, reported similar observations following this method of therapy.<sup>21, 22, 35, 38, 188, 189, 195-225</sup> Hirudin, which is secreted by the leech's salivary gland, can completely prevent coagulation, and in vitro has been observed to cause dissolution of a blood clot. It was on this basis that Termier<sup>191</sup> explained the good results obtained by the use of leeches. Other explanations are based on the production of an increase in phagocytic and bactericidal powers,<sup>229</sup> local blood letting,<sup>223</sup> prevention of venous spasm<sup>205</sup> and general hirudinization.<sup>230</sup> The action of hirudin was experimentally investigated in the Tulane Surgical Laboratory, and leeches were used clinically.<sup>188, 231</sup> There was a rapid subsidence of symptoms following this procedure. At present, its greatest value lies in the treatment of such conditions as portal thrombophlebitis (pyelophlebitis). Some observers<sup>160, 232, 233</sup> have warned against the use of hirudin on the basis that it might produce a liquefaction of the clot, with resulting embolism; this has never occurred in our experience.

Although the use of heparin is of no value, so far as the clot that is already formed is concerned, it is of value in preventing the propagation of a thrombus by decreasing the coagulability of the blood. Murray and Best<sup>161, 162</sup> heparinized 7 patients with pulmonary embolism and infarcts, with recovery in all. Of 28 cases of thrombophlebitis treated with heparin, none developed emboli. Crafoord,<sup>164, 165</sup> on the other hand, did not obtain such favorable results in a similarly small series. Of 20 cases with thromboembolic manifestations, there were only 5 in which the results were good. More recently, Murray<sup>234, 235</sup> reported 81 cases of phlebitis in which heparinization was used. The results in this group were very good, and no patient had pulmonary embolism. He is at a loss to explain satisfactorily these beneficial effects; he states: "The only effect that heparin could have is to prevent extension of thrombosis. It is possible, therefore, that the healing of the lesion already present is allowed to take place and that with prevention of extension of the process the active inflammation recedes and the symptoms disappear with it." The heparin is administered by continuous intravenous injection, and the dosage is regulated so that the clotting time of the blood is maintained at between fifteen and twenty minutes. The patient is kept in bed on the average of one week, and after the acute manifestations have subsided,—by the third or fourth day,—active exercises in bed are encouraged. At the end of this time, he is allowed out of bed, and if no untoward manifestations

develop the administration of heparin is discontinued. Murray and Best state that most of their patients were discharged from six to fourteen days after treatment was instituted.

Graves,<sup>236</sup> in 1906, reported 2 cases of thrombophlebitis of varicosities that were successfully treated with irradiation. More recently, Henschen and Becker<sup>237</sup> advocated roentgen irradiation in thrombophlebitis. They state that from four to twelve irradiations effect a disappearance of the phlebitic symptoms. They advise the use of between 100 and 200 r, applied over the involved extremity, and emphasize that the severer the inflammation the weaker the irradiation should be. They also state that the dose should be decreased or increased according to the location, the type of infection, the age and the general condition of the patient. They believe that the beneficial results are due to the increase in the bactericidal action of the blood stimulation of the reticulo-endothelial system and to the formation of antibodies. They state that the convalescence is definitely shortened. Birgus<sup>101</sup> reports the use of roentgen irradiation in 49 cases of thrombosis, 23 of which were deep, 20 superficial and 6 mixed. The extremity was irradiated over several fields, the dosage varying from 100 to 200 r per field. In superficial processes, one treatment was usually enough. In the acute processes, the treatment was begun with small doses. Birgus states that the duration of the process is shortened by roentgen-ray treatment, the pain and swelling disappear more rapidly, and the pulse and temperature soon return to normal. Halban<sup>238</sup> and Kilbourne<sup>190</sup> advocate using deep x-ray therapy in chronic thrombophlebitis. The latter author emphasizes that roentgen-ray therapy should not be used until the thrombophlebitic process has become chronic.

In previous experimental and clinical investigations, we<sup>1-4</sup> have shown that vasoconstriction of the arterioles and venules plays an important role in producing a persistence of clinical manifestations. The use of vasodilatory measures in the treatment of thrombophlebitis has recently received considerable attention. Murphy<sup>239</sup> and, more recently, Sokolov and Meyers<sup>240</sup> have advocated iontophoresis with acetyl-beta-methyl-choline hydrochloride (Mecholyl). Murphy reported favorable results with his form of therapy in 33 cases of thrombophlebitis. Nineteen patients with thrombophlebitis of the deep veins were treated by this method by Sokolov and Meyers, and improvement was observed in 18. However, only 3 were in the acute stages, although the authors stated that the best improvement was obtained in cases of acute involvement. Vasodilatation by

means of artificially induced fever has been suggested by Weymeersch and Snoeck<sup>241</sup> and by Pitfield.<sup>242, 243</sup> The former authors used injections of sterile milk to produce the fever, and the latter employed injections of typhoid vaccine. Paine and Levitt<sup>244</sup> have recently reported the use of intermittent venous occlusion in the treatment of thrombophlebitis. This method of therapy was employed in 4 cases of acute thrombophlebitis, and in 7 of the chronic form, with relief of pain, tenderness and discomfort. Edema was decreased in some cases but unaffected in others.

In our experience, the best method of therapy in thrombophlebitis of the deep veins is the production of vasodilatation by blocking the regional sympathetic ganglion with procaine hydrochloride, as suggested by Leriche.<sup>245, 246</sup> In 1934, Leriche and Kunlin<sup>247</sup> reported 3 cases of acute postoperative phlebitis successfully treated by this method, and subsequently they<sup>248</sup> reported other cases in which similar results were obtained. Since then, numerous other reports<sup>249-260</sup> have appeared, which attest to the success of this method of therapy.

We<sup>1-4</sup> have shown by experimental and clinical observations that vasospasm resulting from impulses originating in involved venous segments is one of the most important factors in the production of the clinical manifestations of thrombophlebitis. These investigations indicate that the vasospastic influences affect both arterioles and venules. In animal experiments,<sup>261, 262</sup> the volume pulsation in the hind feet of dogs was determined plethysmographically by the sensitive method of Turner. The femoral veins of the dogs were exposed from just proximal to the saphenous entrance below to Poupart's ligament above, and ligatures were placed at these two sites. A chemical thrombophlebitis was produced in the ligated venous segment by injecting a 40 per cent aqueous solution of sodium salicylate. The perivascular tissues in the entire venous segment were then carefully infiltrated with procaine hydrochloride solution, and plethysmographic determinations were made following each of these procedures. In another group of animals, a similar experiment was performed, except that a resection of the corresponding lumbar sympathetic ganglia and intervening chain had been performed twenty-four hours previously. It was invariably found that the volume of pulsation in the foot was markedly decreased following ligation of the femoral vein, and that it almost disappeared following the production of the chemical thrombophlebitis. This effect was always abolished by the interruption of nerve pathways by local infiltration with procaine hydrochloride at the site of the chemical irritation or by resec-

tion of the lumbar sympathetic ganglia and the intervening chain. These experiments demonstrate that the decrease in volume pulsation following chemical thrombophlebitis and periphlebitis is due to vasoconstrictor impulses initiated locally by the chemical irritant and coursing through the sympathetic ganglia to reach the terminal arterial vessels of the extremities. We have also been able to demonstrate clinically that a definite vasospasm exists in thrombophlebitis and that this vasospastic action can be abolished by novocain block of the regional sympathetics. Numerous other clinicians have shown that a localized thrombophlebitic process can initiate a marked vasospasm.<sup>263-284</sup> Indeed, the vasospasm may be so great that the condition appears to be arterial embolism,<sup>257, 264, 266, 271-278, 280-283, 285-290</sup> and in some cases actual gangrene has occurred.<sup>285, 287, 289, 291-294</sup>

In previous publications, we<sup>1-4</sup> have discussed in detail the mechanism by which vasospasm and thrombophlebitis can produce clinical manifestations. Edema may be due to factors that result from vasospasm and increase the amount of perivascular fluid: increased filtration pressure, anoxia of the capillary endothelium and diminution in the flow of lymph. The increase in venous pressure in thrombophlebitis has been repeatedly demonstrated. This obviously increases the filtration pressure, which favors transudation of fluid from the vascular into the perivascular spaces. Because of the associated arteriolar spasm and evidence of diminished vascularity, there probably occurs an anoxia of the capillary endothelium that increases its permeability, permitting an excessive exudation of fluid into the perivascular spaces and thus resulting in the production of edema. Once the fluid gets out of vascular channels in such a case, it has difficulty in getting back because of the increase in the pressure on the venous side. Probably of greater significance in this condition is the fact that the pump, which is responsible for the movement of lymph, is lost. Several investigators<sup>295, 296</sup> have demonstrated that the movement of lymph is dependent on arteriolar pulsations. In the presence of marked vasospasm and increased venous pressure,<sup>261, 262</sup> arteriolar pulsations are reduced to a minimum, and the lymphatic pump is thereby lost. This decrease in lymph flow results in the stagnation of the lymph fluid and the accumulation of proteins in the perivascular fluids, thus setting up a vicious circle, in that the pressure of the perivascular fluid approaches that of the intravascular fluid, tending to prevent absorption of fluid from the perivascular spaces into vascular channels. Such a vicious circle is broken by novocain block of the sympathetic ganglia, which

causes an interruption of the vasoconstricting impulses and thus produces a re-establishment of the normal exchange of the intravascular and perivascular fluids. It has been demonstrated that blocking of the sympathetic nerves increases the flow of lymph.<sup>297, 298</sup> As a result of vasodilatation, the blood supply to the capillaries is increased, anoxia of the capillary endothelium is relieved, and excessive exudation of the vascular fluid into the perivascular spaces is prevented. By the return of the normal arteriolar pulsations, the pump, which is responsible for the movement of lymph, is re-established, and the perivascular fluid is rapidly carried away. Because of this, the edema of the extremity in a patient with phlegmasia alba dolens disappears within a relatively short time after the production of sympathetic-ganglion block. Similarly, the other manifestations associated with thrombophlebitis are relieved, probably by the increased vascularity. Pain, which is one of the most prominent manifestations of thrombophlebitis, is relieved dramatically. Prompt subsidence of fever may also be explained on the basis of a more rapid resolution of the inflammatory process by the increase of vascularity to the involved venous segment.

The results of vasodilatation obtained by novocain block have been reported in previous publications.<sup>1-4</sup> Up to the present, 71 patients have been treated by this method, with prompt relief of symptoms in all. Pain was completely and permanently relieved within fifteen minutes to half an hour after the first injection in 64 cases (90 per cent). Seven patients (10 per cent) required a second injection before the pain was permanently relieved. In 46 cases (65 per cent), the patients were fever free within forty-eight hours after the institution of therapy; in 17 (24 per cent), the temperature returned to normal within three to five days, and in 5 (7 per cent) from six to eight days. There were only 3 cases (4 per cent) in which the pyrexia lasted longer than eight days. Two of these patients had pyrexia resulting from pulmonary infarcts, one lasting twenty-one days and one thirty days, and both recovered completely. One patient had persistence of fever for ten days because of puerperal sepsis. The subsidence of edema was usually rapid. The edema completely subsided within four days or less in 40 cases (56 per cent), in from five to eight days in 23 (32 per cent), in nine to ten days in 6 (8 per cent), and in eleven to twelve days in 2 (3 per cent). Forty-four patients (62 per cent) were discharged from the hospital as cured within four to eight days after the institution of treatment. Twelve (19 per cent) left the hospital from the ninth to the twelfth day

after the institution of therapy, and 7 (10 per cent) remained in the hospital more than twelve days. All remained in the hospital longer than twelve days because of conditions other than the thrombophlebitis. The follow-up observations made on a number of these patients for periods varying from several months to over three years are particularly significant. In none has there been any evidence of recurrence of edema or of other postphlebotic manifestations. This is a particularly important fact in view of the large number of cases that developed postphlebotic edema following other forms of therapy and of the lifelong disabilities consequent to these postphlebotic manifestations.

The technic of lumbar sympathetic block has been described in detail previously,<sup>2, 3, 299, 300</sup> but in brief is as follows:

The patient is placed in the lateral recumbent position. The sites of puncture in the skin are determined by taking points approximately two and a half fingerbreadths lateral to and on a horizontal level with the spinous processes of the first four lumbar vertebrae. Twenty-gauge or 21-gauge lumbar-puncture needles approximately 9 cm. in length are employed. Each needle is inserted vertically until the transverse process of the vertebra is reached. The direction of the needle is then changed slightly to permit deeper insertion either above or below the transverse process, and the needle is inserted approximately two and a half fingerbreadths beyond the transverse process so that its point is near the anterolateral surface of the body of the vertebra where the sympathetic chain lies. Five cubic centimeters of 1 per cent procaine hydrochloride solution is injected through each needle, care being taken to determine previously that the needle is not in a vessel. It has been found that daily blocks should be performed until the temperature returns to normal and remains there. Generally, two or three blocks are sufficient.

Usually, thrombophlebitis can best be treated by conservative measures, and one need not fear the detachment of thrombi with the production of emboli, because as a result of the inflammatory reaction in the vein wall, the thrombus is firmly attached. Conservative measures are sufficient to bring about relief of symptoms and a rapid resolution of the process. Rarely, *radical intervention* is necessary. The indications for radical therapy are suppuration at the site of the thrombophlebotic process, with resultant liquefaction of the clot and the production of infected emboli. Also, in some cases of thrombophlebitis in which the infection extends proximally along the vein wall through

the perivenous lymphatics, a rapid progression of the thrombophlebitic process or a propagation of the clot occurs. In either event, division and ligation of the vessel proximal to the diseased process is imperative to prevent the extension of the process upward and possible fatal embolism and sepsis. A typical example of this is the postpuerperal sepsis in which a thrombophlebitic process involves the venous channels draining the uterus. In such cases, rapid progression of the process, together with the breaking off of infected emboli, is likely to result in a blood-stream infection and fatality. Hunter,<sup>301</sup> in 1784, was apparently the first to apply measures to combat this possibility. He states: "If the inflammation has gone so far as to make the surgeon suspect that suppuration has taken place, then the compress must be put upon that part of the vein just above the suppuration. This I once practiced, and, as I supposed, with success." Lee,<sup>302</sup> in 1865, ligated a vein above the thrombophlebitic process in 2 patients suffering from this condition. In 1880, Zaufal<sup>303</sup> successfully ligated the internal jugular vein in the treatment of pyemia originating in the internal ear. Viereck,<sup>304</sup> in 1901, showed statistically the value of vein ligation in such cases. In a collected series of 108 cases, 89 patients recovered. Apparently Freund,<sup>305</sup> in 1898, was one of the earliest surgeons to apply the method in gynecology. He performed ligation and excision of the thrombosed ovarian vein and broad ligament in 2 cases; these procedures were unsuccessful. Several years later, Bumm<sup>306-309</sup> and Trendelenburg<sup>310</sup> performed venous ligation in puerperal pyemia, the former advocating ligation by the transperitoneal route and the latter by the extraperitoneal route. Ligation or excision of the pelvic veins in the treatment of suppurative thrombophlebitis of puerperal origin has been advocated by Bumm,<sup>306-309</sup> Trendelenburg,<sup>310</sup> Sippel,<sup>311</sup> and numerous others.<sup>312-317</sup> Proximal ligation, with or without excision, has been suggested by numerous others.<sup>271, 318-328</sup> Miller,<sup>329</sup> in 1917, collected 197 cases of puerperal pyemia treated by venous ligation; 15 were approached extraperitoneally, and 182 transperitoneally. The gross mortality was 51.6 per cent. In 1921, Martens<sup>330</sup> reported 11 gynecologic cases of thrombophlebitis in which ligation of the ovarian vein, as well as that of the internal or common iliac vein, was done. In 2 cases, the vena cava was successfully ligated. Recovery followed in 7 of the 11 cases. In puerperal infections, there is considerable controversy concerning the mode of attacking vessels. Whereas gynecologists have largely preferred the transperitoneal approach, surgeons have generally preferred the extraperitoneal

approach. Martens<sup>330</sup> advocates the latter, and Krotoski<sup>331</sup> is of the opinion that the extraperitoneal approach should always be done because laparotomy produces more shock and is dangerous to these patients, who are already very ill. Moreover, there is danger that peritonitis will occur, because the ligation is not always possible in an uninvolved portion of the vein. In cases of thrombophlebitis involving the pelvic veins, it may be necessary to ligate both the internal iliac and ovarian veins. Krotoski<sup>331</sup> suggests that in an extremely ill patient it is best to ligate the internal iliac and the ovarian vein on one side through an extraperitoneal approach, but if the patient continues to have evidence of pyemia, as reflected by persistence of chills and fever, the vessels on the contralateral side should also be ligated. Otherwise, all four vessels should be ligated at the original operation. Ligation of these vessels is frequently lifesaving. If the thrombophlebitic process has extended up from the internal iliac into the common iliac vein and even into the vena cava, it may be necessary to ligate the vena cava above the thrombosed area. Krotoski states that ligation of the inferior vena cava for thrombosis has been performed in 48 cases, without any severe manifestations.

There is considerable controversy concerning the optimum time of operation. Although it is difficult to lay down definite rules, there is certainly a happy medium between the suggestion of Trendelenburg that these patients be operated on immediately after the first chill and the opinion of those who maintain that the operation should not be done until the disease has become chronic. Bondy,<sup>332</sup> Schottmüller<sup>333</sup> and Beuttner<sup>334</sup> advocate ligation of the vein after three chills and the demonstration of anaerobic streptococci in the blood culture. Whereas according to this suggestion the indications seem quite definite, we are in accord with Krotoski<sup>331</sup> that the clinical picture and sound surgical judgment are essential. A patient who looks ill, who has recurrent chills, and who apparently is losing ground should be operated on early; otherwise, a fatality is likely to occur. As early as 1912, Huggins<sup>335</sup> advised exploratory laparotomy in every suspicious case when the diagnosis is in doubt because, in his opinion, the "danger from thrombophlebitis is far more threatening than the risk of operation," if done early. If infarction has occurred, operation should be performed immediately, and procrastination in such cases is likely to mean disaster. The absence of chills in no way precludes the possibility of a septic thrombophlebitis. Krotoski reports that chills occur in only about half the cases. Schollenberg<sup>336</sup> states that, on the basis of the material

in the Zurich University women's clinic, in the cases in which a second chill was taken as an indication for operation, 67.4 per cent of patients were operated on unnecessarily, and in cases in which a third chill was taken as an indication for operation, 56.2 per cent were operated on unnecessarily. The importance of absence of chills has also been emphasized by Miller.<sup>314 329</sup>

The technic of the operative procedure and the method of approach vary according to individual operators. A distinct advantage of the transperitoneal technic is that it is possible to visualize and ligate all four of the uterine vessels through a single incision. The operation does carry a higher risk, however, because of the greater shock associated with the transperitoneal approach, and also because of the potential danger that infection of the peritoneum will occur from division of an infected vessel. It is imperative that the vessel be isolated above the point of involvement, and not only that the vessel be divided but also that a segment of vein be removed. The former is of significance, because only in this way can the propagation upward and the liberation of the emboli be prevented. The latter is necessary to obviate the extension of micro organisms through the perivascular lymphatics, which could continue if the vein is ligated only and is not divided. It is extremely desirable not only to divide the vein but also to extirpate a portion of it, since in this way the perivascular lymphatic extension can be more effectively stopped. Krotoski<sup>321</sup> emphasizes the value of careful examination of the urinary tract, because in this way it is possible to determine not only kidney involvement, but also the location of the lesion. In a case, which he reported, with involvement of the right side, there was extensive infection of the ureter and almost complete blockage on that side because of the associated inflammatory process extending from the ovarian vein. This would be a valuable procedure in determining which side should be operated on in the extra-peritoneal approach. At the time of operation, it may be desirable to drain the area of the involved vein, as has been emphasized by Krotoski. In one of our cases with suppurative thrombophlebitis of the right ovarian vein, transperitoneal exposure and resection of a portion of the vein resulted in cessation of pyemic manifestations and subsidence of fever.

Kraussold,<sup>327</sup> in 1878, successfully ligated the femoral vein in a patient who developed a suppurative thrombophlebitis following a thigh amputation. In a previously reported case,<sup>3</sup> ligation of the femoral vein, because of a suppurative thrombophlebitis in the popliteal vein, was followed by immediate disappearance of septic manifestations

Griess,<sup>328</sup> in 1913, successfully performed thrombectomy and excision of a segment of the femoral vein in a case of postpuerperal septic thrombophlebitis. Rost,<sup>329</sup> in 1916, reported 2 cases of leg amputation followed by thrombophlebitis in which ligation of the femoral vein was successful. Numerous others<sup>315 340 341</sup> subsequently reported successful proximal venous ligation in femoral thrombophlebitis and emphasized its therapeutic and prophylactic value. More recently, cases of femoral thrombophlebitis successfully operated on were reported by Pool and McGowan,<sup>323</sup> and Van Duyn and Van Duyn.<sup>342</sup>

Proximal ligation has also been employed for thrombophlebitis of the mesenteric veins, and one of the earliest cases was reported in 1907 by Brunner,<sup>343</sup> although Gerster<sup>344</sup> had previously reported 2 successful cases in which exposure and evacuation of the thrombosed vein had been done. Wilms<sup>345</sup> advocated ligation of the veins in the ileocolic angle in cases of pylephlebitis and was successful in treating a case in this manner. Braun<sup>346</sup> advised ligation of the ileocolic vein in such cases, and performed this procedure successfully in 2 patients. Melchior<sup>347</sup> was able to collect from the literature 13 cases in which the Braun procedure had been used. In 8 cases in which it was employed at the time of appendectomy, all the patients recovered. In the 5 cases in which a secondary operation was necessary, there were 4 deaths.

**Phlebothrombosis** In contradistinction to thrombophlebitis of the deep venous system, phlebotrombosis of these vessels occurs more insidiously and is frequently unassociated with marked clinical manifestations. Instead of a pyrexia, with pain in the extremity and an associated swelling and edema of the extremity, patients with phlebotrombosis have relatively little pain, usually little or no fever and generally no swelling. Of greater diagnostic importance is the increasing pulse rate—the "stepladder pulse" first emphasized by Mahler.<sup>348</sup> When pain is complained of, it is usually in the calf or in the sole of the foot, because, as Neumann<sup>349</sup> has shown, the thromboses are generally limited to the veins of the calf or foot. He found that the foot veins were involved in 71 per cent, the leg veins in 87 per cent, and the thigh veins in 22 per cent. Solitary thrombosis occurred in the calf veins more frequently than in other veins. Solitary calf-vein thrombosis occurred in 29 per cent, solitary plantar-vein thrombosis in 12 per cent, and both calf-vein and leg-vein thrombosis in 57 per cent. Rossle<sup>61</sup> in post-mortem studies found that 25 per cent of all cases had calf-vein thromboses. Of greater importance than spontaneous pain is that elicited by pressure

on the plantar aspect of the foot, on the medial aspect of the foot just beneath the medial malleolus or in the calf, or by forced dorsiflexion of the foot in the popliteal region, the so-called "dorsiflexion sign of Homans." On the basis of extensive anatomic studies, Bragard<sup>350</sup> found that examination of the lower end of the femoral vein was best performed by having the patient sit with his legs separated and externally rotated. This causes the hamstring muscles to be rolled to the inner side, bringing the femoral vein into a more superficial position. The examiner sitting in front of the patient can palpate with both hands the two femoral veins in their lower portions and can determine better whether there is tenderness and induration. For examination of the calf veins, he advocated grasping the muscles of the calf behind the tibia and eliciting tenderness by firm pressure. Whereas these patients do not appear to be so ill as those with thrombophlebitis, the possibility of serious trouble is much greater; because of the lack of the inflammatory reaction in the vein wall, the thrombus is either only loosely or not at all attached to the vein wall, and the chance of its becoming detached, with resultant infarction or massive embolism, is considerable.

As in phlebothrombosis of the superficial veins, *conservative therapy* is indicated in the absence of rapid progression and evidence of infarction. The application of elastic bandages to the involved extremity, extending from the metatarsal phalangeal joints up to the groin, is desirable. The thigh should be flexed and elevated to an angle of 45°, and the leg and foot should be elevated above the level of the knee. Passive and slightly active motion of the foot at the ankle is encouraged. After twenty-four to forty-eight hours, the motion can be made against resistance. This favors the movement of the blood in the deep veins. The application of a heat tent over the lower extremities is of great value, not only because of the support it offers to the bedclothes, but also because of the vasodilatating effect of the heat.

Hirudinization and heparinization have been employed and may be of value in these cases of deep-vein phlebothrombosis. Whereas heparinization has been advocated prophylactically and therapeutically, it seems to us that its value depends on the prevention of propagation of thrombi and the production of emboli. For such purposes, it appears that proximal ligation is a much safer and more reliable procedure.

Vasodilatation, by means of vasodilatory drugs such as papaverine, anaphoresis with Mecholyl or the use of sympathetic block is of value in cases of phlebothrombosis as well as in those of thrombophlebitis. The results obtained are not so dramatic as those in thrombophlebitis because such

patients do not have the marked pain, swelling and fever that patients have with thrombophlebitis.

Whereas the manifestations in phlebothrombosis of the deep veins may subside completely under conservative therapy, because the thrombus is loosely attached, it is frequently necessary to resort to *radical therapy*. This is indicated in those cases in which there is rapid progression of the thrombotic process, as evidenced by upward extension of tenderness, a persistent elevation of pulse rate, and fever. The development of an infarct is an extremely important indication for radical therapy. Zink<sup>351</sup> states that in 70 per cent of cases with fatal pulmonary embolism there was a hemorrhagic infarct, indicating a previous embolism. Bahls<sup>357</sup> emphasizes the importance of restlessness, together with an elevation of the pulse, in a patient who is otherwise doing well. The patient senses that something is wrong. Bahls believes that these are premonitory manifestations of a fatal pulmonary embolus. Other indications for radical therapy, as emphasized by Homans,<sup>168</sup> are the failure of the subsidence of symptoms under conservative therapy and the return of manifestations after the patient is allowed up and after the symptoms have originally subsided. Sears<sup>326, 327</sup> believes that all patients with thrombosis of the calf veins should have proximal-vein ligation as soon as the diagnosis is made. Thrombectomy has been advocated by Låwen<sup>273</sup> and Kulenkampf,<sup>352</sup> the former extracting the thrombus through an opening in the femoral vein, the latter through the saphenous opening. Both attempt to save the deep venous system by suture of the vein wall. Lange<sup>353</sup> also advocates thrombectomy, but Fründ<sup>354</sup> states that ligation should also be done. Leriche and Geisendorf<sup>355</sup> performed thrombectomy but also resected a segment of the femoral vein. Whereas, theoretically, thrombectomy and suture of the vein seem desirable and although the experimental work of Hintze and Zollenkopf<sup>356</sup> appears to support the contention that these veins again function, we believe not only that it is unnecessary to attempt to save the vein but that it is actually dangerous. In one of our cases with extensive phlebothrombosis of the deep venous system and pulmonary infarction, the common iliac vein was ligated at its junction with the vena cava, and a concomitant resection of the third and fourth sympathetic ganglia performed. The patient recovered rapidly and has remained free of all previous manifestations. Homans<sup>168</sup> suggests saving the vein and heparinizing the patient. In one of his cases in which this was done, embolism recurred, thus making it necessary to divide the common iliac vein, following which embolism ceased and the leg became functionally useful. This case, it seems

## THE MANAGEMENT OF GONORRHEA\*

## VI. The Sulfonamides

## Neisserian Medical Society of Massachusetts

## SULFANILAMIDE

**S**ULFANILAMIDE should not be used in the treatment of gonococcal infections. Early reports of its high efficiency were commonly in error because of failure to evaluate cure by cultural methods. The immediate clinical response was good in a large number of cases, but subsequent clinical relapse was common, and cultural studies made by many later observers disclosed that innumerable asymptomatic carriers were being produced. These carriers remain potential spreaders of infection for many months.

## SULFAPYRIDINE

Sulfapyridine cures a much higher proportion of cases, but it causes more serious reactions than sulfanilamide does. Since a newer drug, sulfathiazole, is equally effective and causes few immediate reactions, this should be, at present, the drug of choice.

## SULFATHIAZOLE

There is much excellent evidence, based on careful and extensive cultural study, that sulfathiazole cures as high a proportion of gonococcal infections, in either sex, as any other sulfonamide now available. Of the failures, some do not respond at all, and the remainder either relapse or become asymptomatic carriers for variable periods.

Although many excellent treatment schemes have been and are still used, the following dose has the advantage of being simple and rapidly effective: 2 gm. daily for ten days; the daily dosage is usually divided into four doses of 0.5 gm. every four hours. The dose for children is 30 mg. per pound of body weight, but the total daily dose should not exceed 2 gm. The fluid intake should not be restricted.

In men, if there has been no clinical improvement by the fifth day, the drug should be discontinued for the time being, for its continued

use will accomplish no favorable result. The clinical picture in women is so often confused by other conditions, however, that it is the rule to give the full course in every case and to depend on bacteriologic study for proof of response.

Infections that fail to respond to one course of sulfathiazole may often be cured by a second course, similar to the first, following a rest period of a week or ten days. More than two consecutive courses of the drug, however, are of questionable value.

In definite drug failures, careful search should be made for the possible cause of failure, and recourse should be had to local treatment. In some cases, fever therapy may be indicated.

The patient should be kept under observation during the course of sulfathiazole therapy because reactions may occur as a result of the administration of any of the sulfonamides. If there is persistent vomiting, rash or other severe reaction, the drug should be discontinued. Moderate nausea will be reported by an occasional patient, but is not ordinarily a cause for stopping the drug. There is no need for determining blood levels when the recommended dose is used, for concentration of the drug in the blood seems to have no relation to the clinical or bacteriologic result. Blood counts and hemoglobin determinations may be indicated for some patients.

## DETERMINATION OF CURE

When treatment has been concluded, the patient should be directed to abstain from unprotected sexual contacts for at least three months. Relapse should ordinarily occur within this period, if it is to occur. If cultural facilities are available, cultures of prostatic secretion and urine sediments in men and of exudates from the cervix and the paraurethral (Skene's) glands in women should be made from four to six times during this period. Smears, also, should be examined, but negative smears should not be relied on as evidence of cure. More than 3 to 5 pus cells per oil-immersion field in prostatic secretions are significant of prostatic infection of some kind (not necessarily gonococcal), but freedom of prostatic secretion from pus is not evidence of cure of a gonococcal infection.

In some women who have gonorrhea, the vaginal discharge continues or reappears after treatment

\*In 1934, the Neisserian Medical Society of Massachusetts undertook the publication, in the *New England Journal of Medicine*, of a series of papers on the management of gonorrhea.<sup>1-5</sup> Shortly after the appearance of the fifth paper, in 1937, the sulfonamides were added to the therapeutic armamentarium. Until now, the Society has not been satisfied that enough data were available concerning the performance of these new drugs to permit sound conclusions about their worth. This sixth paper in the interrupted series is now presented as an expression of the Society's opinion concerning the place that the better of the sulfonamides should have in the therapy of gonococcal infection.

Since the American Neisserian Medical Society was about to issue a somewhat similar statement based on its wider experience, the two statements were combined, and will appear in essentially identical language. That of the American Neisserian Medical Society will appear in the *Transactions* for 1941.

has been stopped. It is worth while to search for other causes in these cases before concluding that the gonococcal infection has not been cured, or that the patient has been reinfected.

#### SOME VALUABLE ADVANTAGES TO BE GAINED

It is of the greatest advantage to begin treatment of infections in women immediately, without waiting for laboratory confirmation of the diagnosis, if the history of exposure or a known infection in the sexual partner, in addition to clinical evidence in the patient, points to gonococcal infection. Prompt treatment usually prevents extension of the infection into the pelvic cavity, or controls it if it has already occurred. The risk of permitting an infection to spread upward is much greater than the risk of using the drug in a case that may not be a gonococcal infection. Smears and, if possible, cultures, should be made at the first visit in every case, however, since they may help to establish the diagnosis. Once treatment is begun, they are likely to be negative.

### CLINICAL NOTE

#### THE CONTROL OF POSTOPERATIVE TONSILLAR HEMORRHAGE\*

JOHN R. NOYES, M.D.†

BROCKTON, MASSACHUSETTS

**B**LEEDING following tonsillectomy usually occurs either within twelve hours following operation or between the fourth and sixth postoperative days. When it occurs during the latter period, it is usually the result of a slough due to imperfect healing. The bleeding is apt to be of the slow capillary type but is inclined to be persistent, and it is often difficult to find any distinct vessel from which it is coming.

Since general surgical principles have been applied and ligatures liberally used at the time of operation, the incidence of hemorrhage has been greatly reduced, but the condition still occurs frequently enough to keep the surgeon constantly on the alert, and anything that will make this troublesome problem easier should be welcomed.

Many methods, both mechanical and chemical, have been used in the past, but none has seemed quite ideal. The following procedure for controlling such hemorrhages was developed entirely by accident.

In the summer of 1920, I performed a tonsillectomy on an 18 year-old girl. Five days later, I was

Since sulfathiazole seems to cure a high proportion of gonococcal infections in both sexes, the prompt use of this drug should result in an early "chemical quarantine" of many of the infections. Every effort should be made, however, to keep the patient under sexual control for at least three months after apparent cure.

There is reason to be optimistic over the eventual control of gonorrhea, for it should now be possible to cure the disease much faster than it can spread. The medical profession has at hand a medium through which, if properly used, one more dangerous and prevalent communicable disease may be added to those that were once serious public health problems.

called to her home on account of bleeding from the throat. Examination showed that it was coming from the left tonsil wound, from what appeared to be a piece of tonsillar tissue.

Novocain was injected around the supposed piece of tonsil so that it could be removed, because it is well known that the removal of such tabs will sometimes stop bleeding. Immediately after the injection, the bleeding ceased. Further examination showed the supposed tonsillar tab to be only an organized clot.

This experience was impressive, and it led to the adoption of the same method in every case of delayed hemorrhage that I have treated within the last twenty years, a total of 126 cases.

Bleeding was promptly and permanently checked in every case except one. The patient in this case was a forty three year-old woman with a systolic blood pressure of 260. Hemorrhage occurred six hours after operation. It was necessary to place a ligature around the bleeding point.

The first step in this method is to gain the cooperation of the patient; this is time well spent. Next, the clot that is always present at the site of bleeding is swept out with a piece of gauze on a curved hemostat. The bleeding point is found if possible, and 1 or 2 cc. of a 1 per cent novocain solution containing 0.06 cc. (1 minim.) of 1:1000 adrenalin solution per cubic centimeter is injected *superficially* around it. If the bleeding point cannot be found, the solution is injected at various places in the wound until bleeding stops.

\*Read before the New England Oto-Laryngological Society.

†Consulting otolaryngologist Brockton Hospital and Jordan Hospital, Plymouth.

Ten cubic centimeters can safely be used. A syringe, similar in type to the small one commonly used by dentists, holding a 5-cc. ampule of sterilized solution, is used. The same syringe is used for tonsillectomies under local anesthesia. This method can be employed with a minimum of discomfort to the patient, and can easily be applied without anesthesia in quite young children.

The control of the bleeding is effected by the mechanical pressure produced by the solution, together with the vasoconstrictor action of the adrenalin.

The danger of infecting the deep tissues of the neck when injecting through a septic field has always been kept in mind, but no infection has occurred. In only a few cases have I painted the area to be injected with an antiseptic solution.

This method has been recommended to several associates, and all who are using it report uniformly good results. Its chief value lies in its simplicity and effectiveness. I am now using it to control bleeding at the time of the removal of tonsils, and also for spontaneous nasal hemorrhages.

47 West Elm Street

## MEDICAL PROGRESS

### ARTIFICIAL FEEDING OF INFANTS\*

R. CANNON ELEY, M.D.†

BOSTON

THE present method of artificial infant feeding has become as simplified as the earlier percentage methods were complicated. Yet, in spite of this advantage, one is frequently surprised at some of the types of feeding that are encountered both in private practice and in public clinics. A consideration of the nutritional needs of the normal infant, the method of determining the formula, the expected vitamin requirements and the age periods at which food substances other than milk are added to the diet is therefore presented.

In determining the nutritional requirements of a normal infant, one must consider not only the structural requirements—that is, protein, fat, carbohydrate minerals and water—but also the energy requirements for basal metabolism, exercise, growth and repair, and loss through stools (a total of approximately 40 calories per pound).

The protein requirements of the normal infant are satisfied by a daily minimum of 1.5 gm. per pound of body weight, although on rare occasions it may be preferable to increase this amount to 2 gm. Cow's milk conveniently contains this amount of protein in 1½ ounces of milk, so that it becomes quite simple to multiply the weight of the infant by one and a half and thus derive the number of ounces of cow's milk required to meet the protein needs of the baby. This minimum requirement of cow's-milk protein is somewhat greater than that of human-milk protein, since cow's milk is relatively deficient in certain amino acids.

All articles in this series will be published in book form; the current volume is *Medical Progress: Annual, 1940* (Springfield, Illinois: Charles C Thomas Company, 1941. \$4.00).

\*From the Department of Pediatrics, Harvard Medical School, and the Infants' and the Children's hospitals.

†Associate in pediatrics and communicable diseases, Harvard Medical School and Harvard School of Public Health; associate visiting physician, Infants' and Children's hospitals.

Although fat and carbohydrate furnish a certain amount of the structural requirements, they are primarily employed as available sources of energy. The percentages of fat (3.5 to 4.0) present in both mother's and cow's milk are approximately the same, and in the healthy infant can usually be tolerated without difficulty. In fact, when an infant is artificially fed, the percentage of fat in the formula is less than 3.5 to 4.0, owing to the dilution of the whole milk by the addition of water. Carbohydrate, which in the artificially fed infant should afford approximately one third the total number of calories, may be in any clean and inexpensive form such as cane sugar, Karo corn syrup and Dextri-Maltose. Although the sugar present in human milk is lactose, and although many are of the opinion that lactose is unquestionably the sugar of choice for these infants, it has been more than difficult to demonstrate any appreciable difference between infants receiving this sugar and those receiving a less expensive form, such as corn syrup.

The total fluid requirement for the normal infant varies, according to the age and weight of the baby. In the early months of life, and particularly during the first few days of life, this need can be satisfied by 2½ to 3 ounces per pound of body weight daily. As one might expect, this requirement is subject to change, such as in hot weather and in the presence of diarrhea, when large amounts of fluid are being lost. The mineral and salt content of cow's milk, although much greater than that of mother's milk, is usually tolerated very well by the infant and, except in the presence of pathologic conditions, adequately supplies the need.

When one considers the vitamin content of milk, exclusive of irradiated milk or milk ob-

tained from a herd receiving irradiated yeast, vitamins A and B are usually adequate, but C and D are present in such small amounts that for practical purposes they must be considered inadequate. The average daily requirements of these substances can be met by the addition to the diet of  $1\frac{1}{2}$

TABLE 1. Commonly Employed Sources of Vitamins

SUBSTANCE	VITAMIN			
	A int units	B <sub>1</sub> int units	C mg	D int units
Human milk (quart)	2000	200	50	100-200
Cow's milk, pasteurized (quart)	2000	150	0-4	20
Cow's milk, evaporated (quart)	4000	300	None	40

\*Also vitamin G (B<sub>2</sub>), 160 Sherman units

ounces of orange juice or 3 ounces of tomato juice (25 mg. or 500 international units of vitamin C) and 2 teaspoonfuls of cod-liver oil (400 international units of vitamin D). Table 1 presents the more commonly employed sources of these vitamins.

Since the energy requirements of a normal infant have already been mentioned, a second table

TABLE 2 Average Energy Values and Measures of Food Substances in the Infant's Formula.

FOOD SUBSTANCE	ENERGY VALUE cal /oz	MEASURE teaspoonfuls/oz
Mother's milk	20	2
Cow's milk (4 per cent fat)	20	2
Home skimmed milk	13	2
Fat free milk	10	2
Cane sugar and Karo corn syrup	120	2
Lactose	120	3
Decalin Maltose	120	4
Starch and uncooked cereal	100	3
Cod liver oil	270	2
Orange juice	15	2

(Table 2) presents the caloric values of the various substances that constitute the diet of the young infant.

Attention should also be directed to the method employed in determining the actual amounts of milk, carbohydrate and water that constitute the formula. The daily caloric need is first obtained by multiplying the weight of the baby by a standard number of calories. In general, 45 to 50 calories per pound are adequate during the first months of life, whereas 40 to 45 calories are essential during the second half of the first year. As previously stated, the protein requirements are usually satisfied by  $1\frac{1}{2}$  ounces of cow's milk per pound of body weight, so that if one assumes that the baby weighs 8 pounds, one would need 12 ounces of cow's milk. This would not only contain the needed protein and minerals but would

also furnish 240 of the necessary 360 calories, leaving the balance of 120 to be supplied by added carbohydrate. (It is advisable that approximately two thirds of the total caloric requirement be supplied by the milk and only one third by carbohydrate.) The total fluid volume is obtained by adding a quantity of water so that the resulting amount is approximately  $2\frac{1}{2}$  ounces per pound of body weight. To obtain this, one would add about 7 ounces of water, and the formula would then be:

Whole milk	12 oz (240 calories)
Carbohydrate	1 oz. (120 calories)
Water	q. s. ad 20 oz. ( 0 calories)
	20 oz. (360 calories)

As the infant gains in weight, it becomes necessary to alter the formula to meet the increased demands. For example, when the baby reaches 12 pounds the formula would be:

Whole milk	18 oz (360 calories)
Carbohydrate	$1\frac{1}{2}$ oz. (180 calories)
Water	q. s. ad 30 oz. ( 0 calories)
	30 oz (540 calories)

The formula is prepared in the following manner:

Dissolve the specified amount of carbohydrate in the water, and add the solution to the milk. Boil this mixture over direct heat for three minutes, stirring constantly. When the mixture has cooled, pour it into a sterile graduate, preferably glass, or some measuring container, and add to this a sufficient quantity of sterile water to make the final volume. Divide the formula into the desired number of feedings by pouring the necessary amount into sterile bottles, which are then capped with sterile rubber stoppers. As soon as the bottles have cooled, they may be placed in the ice chest until needed. The number of feedings, or bottles, given to the baby each day depends not only on the age and weight but also somewhat on the infant itself, for it is certainly true that some babies gain and do well on a small number of daily feedings. However, the baby usually requires one feeding every four hours during the first few weeks of life, after which five daily feedings are ample.

Formulas prepared from evaporated or dried milk have found a useful position in infant feeding, and certainly there are occasions, as well as circumstances, when they can be employed to advantage. The chief objection to the use of these proprietary forms of milk is that it frequently becomes necessary to alter the protein or especially the fat content of the infant's formula (such as in the presence of an infection), and if such forms of milk are being employed this alteration

becomes practically impossible. Another objection is that there are no legal standards for the grade of milk used in these preparations. It is a common impression that evaporated milk produced by a given manufacturer is always the same, but this is not necessarily true: if the company is producing its product in several sections of the country, the grade of the milk varies according to the grade of the milk of the locality. In spite of these differences, experience has shown that evaporated milk may be employed as a satisfactory source of food for infants. When using it in preparing a formula, one has only to remember that half the water has been removed from the milk in its preparation, and that when this is replaced each ounce of the mixture is equivalent to an ounce of cow's milk. For example, if evaporated milk were used in the previous formula, the amounts would be: evaporated milk, 9 ounces; carbohydrate,  $1\frac{1}{2}$  ounces; and water, sufficient to make 30 ounces.

This simple mathematical determination of an infant's food requirements would make infant feeding a simple procedure if the resulting equation could be applied to all babies. Unfortunately, however, this cannot be done, since the requirements for each baby vary over a wide range, depending on the infant's ability to utilize the food, his activity and so forth. For example, one baby may gain and do well on 35 calories per pound, whereas another baby of the same age may require 50 calories per pound. Since it is impossible to know this beforehand, and since babies on a high-calorie intake are apter to develop digestive disturbances than those on a low-calorie intake, it is always safer, and therefore advisable, to start an unknown infant on a low-calorie intake and then to increase the diet should it prove inadequate. Again, an undernourished infant usually needs a larger amount of food per pound of body weight than a relatively normal baby, and as a rule the requirements more nearly approximate those based on the expected weight rather than those based on the actual weight.

Failure of a baby to gain on a well-balanced formula does not necessarily imply that the formula per se is at fault, and it certainly should not be considered an indication to change to something else—as it too frequently is. Any change in the formula should not be undertaken until after a thorough physical examination of the baby has been made and all evidence of infection—acute, chronic, enteral or parenteral—has been excluded. The formula is rarely guilty.

In those cases in which the infant has been breast-fed, if even for only a few days, little difficulty will be encountered when a formula feeding is substituted for a breast feeding. If necessary,

one can replace one breast feeding by one formula feeding each day until the baby is weaned. On occasion, the mother may be unable to nurse her baby, and it becomes necessary to feed the infant artificially from the very beginning. In such cases, it is advisable to prepare a weaker formula, that is, one that contains less than 20 calories per ounce, since the digestive system of the newborn infant may not be able to tolerate a stronger mixture. An adequate formula for this purpose is one containing equal parts of milk and water and less carbohydrate than usual: for example, whole milk, 10 ounces; carbohydrate,  $\frac{1}{2}$  ounce; and water, sufficient to make 20 ounces. This formula may be offered two or three times on the second day of life, four times on the third day, and every four hours thereafter. Once this type of feeding has been satisfactorily established, the strength of the formula may be gradually increased until each ounce contains 20 calories.

I have already mentioned the addition of vitamins to the dietary and now need to consider only the periods at which other foodstuffs may be introduced. Although there may be rare cases in which it is necessary to add other foods to the diet, most infants do not require these substances before the fifth month of life. At this time, cereal may be added at the 10-a.m. and 6-p.m. feedings, being served with some of the formula poured over it. As soon as this is accepted by the baby, a small amount of stewed fruit, usually in the form of applesauce, may be included at 6 p.m. Strained vegetables, egg yolk and beef juice are frequently given by the sixth or seventh month. With the addition of these foods, one should gradually reduce the added carbohydrate in the formula, since these calories are available through the additional food. Experience has shown that it is not advisable to remove all the sugar at once but to reduce it every few days until it has been entirely removed. By such a process, one is often able to omit the formula and have the baby on three daily feedings by the ninth or tenth month of life.

I have deliberately omitted the quantities of each food substance that the baby should take. The baby is a very good judge himself, and if one only begins with reasonably small amounts and increases them as the baby shows his inclination and desire for more, one will go far in having not only a happy baby but also a happy mother. To say that the baby *must* take one tablespoonful of one substance and two of another at a specified feeding is as absurd as insisting that each baby *must* have a quart of milk a day. Insistence on such impractical principles as these usually results in an unhappy and stubborn infant who soon rebels against all his food.

## CASE 27321\*

### PRESENTATION OF CASE

An eight and-a-half-year-old girl was brought to the Outpatient Department with a complaint of vomiting. Her past history was not remarkable except for an appendectomy five years previously, and occasional attacks of abdominal pain and vomiting since that time. A mild upper respiratory infection had been present for the previous week.

While on a trip with her family two days before admission, the child had a strawberry milk shake and fried clams, other members of the family had the same type of food at that time. About half an hour later, she began to complain of low abdominal pain, and she vomited once. That night, she vomited three times but did not appear to be very sick. On the following morning, the mother gave her an enema, with a moderate fecal return. This was followed with another shortly thereafter, without results. During that morning, she ate nothing and vomited three times. The family physician was consulted, and advised an additional enema, which was unproductive, and a mild laxative, which was immediately vomited. The child had no fever, and played normally the rest of the day. On the day of admission, the abdominal pain seemed very much diminished, but she vomited several times. She passed no feces or gas by rectum. The family physician was called again that morning. After a flat plate of the abdomen was taken, which showed dilated loops of bowel, he advised that the child enter the hospital.

Examination revealed general dehydration, with sunken eyes, slight cyanosis of the lips and rapid, shallow respirations. The abdomen was distended and tympanic, with moderately active peristalsis. There was no spasm or tenderness by abdominal or rectal palpation.

The temperature was 102°F, the pulse 120, and the white cell count 15,000.

Within a few minutes after admission, a marked change in the patient's condition became apparent. The pulse became imperceptible, and cyano-

sis became more marked. Twice, she vomited large amounts of thin, brownish fluid material, which on later examination proved to be guaiac positive. There was no fecal odor to this material. During the next few minutes, her extremities became cold and pulseless, her breathing became more rapid and shallow, and she became disorientated. Restlessness became more marked, and the patient became comatose. Respiration and heart beat stopped apparently at the same time. There was no response to the intracardiac administration of adrenalin. Artificial respiration was attempted without success. Exitus occurred approximately twenty minutes after arrival at the Outpatient Department.

### DIFFERENTIAL DIAGNOSIS

DR ROBERT R. LINTON: There are certain things in the past history of this patient that are of interest and bear a definite relation to the outcome. The fact that she had an appendectomy five years before admission should be noted, and also the fact that she had abdominal pain and vomiting on occasions after the appendectomy. I do not believe her mild upper respiratory infection had anything to do with her exitus. Nor do I believe the strawberry milk shake and fried clams eaten prior to the onset of the terminal illness had any bearing on her condition, since she vomited within half an hour after taking them. It is possible that the taking of food, and I think it could have been any kind of food, might have precipitated her trouble. The most important thing to me is the fact that she had complete obstruction shortly after the onset of her illness. She had a number of enemas which were unproductive. She had a mild laxative, which was vomited, so that we do not know whether it would have produced results or not—probably not. Her local doctor showed wisdom in having a flat abdominal x-ray plate taken; this is a useful diagnostic procedure in abdominal conditions, especially when one may be dealing with intestinal obstruction. It is reported that the plate showed dilated loops of bowel. I am sorry we cannot see that plate to determine whether the dilated loops were small bowel or large bowel, since such a differentiation is of considerable importance in making a decision of what the trouble is.

The patient was admitted to the hospital, and according to the physical examination, she was extremely sick. The cyanosis of her lips, I think, is a very important point. Her temperature was 102°F, and she had a pulse of 120. The abdomen on examination showed distention, which would go with the x-ray report of dilated intestinal

\*This case is presented through the courtesy of the Children's Hospital Boston.

loops. I am a little surprised that she had moderately active peristalsis. I should almost think she was too sick for active peristalsis to have been present. At least, peristalsis rules out the possibility that she had peritonitis, since active peristalsis in the presence of peritonitis does not occur. She had no spasm or tenderness by abdominal or rectal examination. That also helps one in ruling out peritonitis, although I have seen cases of generalized peritonitis in which there was no spasm and practically no tenderness. The white-cell count was 15,000, which is consistent with either peritonitis or intestinal obstruction.

The extraordinary thing about this patient is that she died so shortly after admission to the hospital. Because she was vomiting large amounts of fluid, one wonders a little whether she died from suffocation following the aspiration of vomitus, but the story we have is not of this nature. The history describes the vomitus as thin, brownish fluid, a description which is typical — except for the fact that there is no mention of a fecal odor — of intestinal obstruction and probably small-bowel obstruction. It is possible that she was in such dire straits from dehydration and electrolyte loss that she could succumb as quickly as this. I have seen such deaths occur. I remember seeing a man in the Emergency Ward who was admitted in a condition very similar to that of this patient; he succumbed while being sent from the Emergency Ward to the operating room, so that people can die quickly of intestinal obstruction. The fact that the brownish fluid was guaiac positive is further evidence of intestinal obstruction. Such fluids are usually guaiac positive, owing to small capillary hemorrhages and stasis within the vascular system of the bowel.

My belief is that this patient died of acute intestinal obstruction, which resulted from the fact that a loop of ileum had become adherent to the appendectomy scar in the right lower quadrant.

A PHYSICIAN: Could she have had a pancreatitis?

DR. LINTON: I have never seen pancreatitis in such a young person.

DR. MILTON J. QUINN: Could she have had a condition associated with a Meckel's diverticulum?

DR. LINTON: If she had had, the diverticulum might have perforated, thus causing a peritonitis. It is possible, of course, to have intestinal obstruction or intussusception from a Meckel's diverticulum. I suppose I am assuming a little too much in thinking that the surgeon who operated on her five years previously ruled that out. It is possible that he did not, and there might have been a Meckel's diverticulum. It is a distinct

possibility and should have been included in the differential diagnosis.

#### CLINICAL DIAGNOSIS

Intestinal obstruction, acute.

#### DR. LINTON'S DIAGNOSIS

Intestinal obstruction due to postoperative adhesions.

#### ANATOMICAL DIAGNOSES

Intestinal obstruction, acute, complete.

Volvulus of terminal ileum.

Old adhesions between ileum and abdominal wall at site of old appendectomy incision.

Pulmonary edema, severe, acute.

Bacteremia (unidentified, anaerobic, spore-bearing, gram-positive bacillus), agonal.

#### PATHOLOGICAL DISCUSSION

DR. SIDNEY FARBER:\* Dr. Linton's first suggestion was the finding that we made at post-mortem examination. A volvulus of the small intestine passed around old adhesions, which connected the ileum to the abdominal wall at the site of the old appendectomy incision. The small bowel above the point of obstruction was very much distended. The walls of the small bowel were edematous. In its lumen, there was found about 500 cc. of rather thin dirty fluid, which had a fecal odor. On microscopic examination, the discolored portion of ileum was not necrotic in all places: there were areas where the mucosa was intact. The impression given by gross and microscopic examination was that the obstruction had been an intermittent affair.

The spleen was about half the normal size. Throughout the body, there was evidence of rather widespread vascular collapse. The veins all through the abdominal cavity were greatly distended with blood. The lungs were the site of marked edema.

The brain was approximately of normal weight and showed externally only moderate edema. On section after the brain was fixed, however, there were a number of small areas of destruction scattered throughout the brain, giving a Swiss-cheese appearance. These areas could be correlated with the presence in the lung on culture and in various organs in the body on section of gram-positive, spore-bearing bacilli, which looked like *Clostridium welchii* but which did not behave like this organism on guinea-pig protection studies. The organisms must have reached the blood stream just before death. There was no cellular reaction to these bacteria anywhere in the body.

\*Assistant professor of pathology, Harvard Medical School; pathologist, Children's Hospital.

In summary, the postmortem showed acute intestinal obstruction caused by volvulus brought about by old adhesions between the ileum and the abdominal wall at the site of the old appendectomy wound.

DR. LINTON: It seems to me that too many cases of this nature are occurring. We have had a number, and I have seen one very recently. It is a condition that can be prevented, and it merely means a careful toilet when a surgeon is closing the peritoneum. In an adult, there is practically always sufficient omentum to interpose between the loops of the small bowel and abdominal wound. In a child, the omentum is not so large, and one cannot always do it so readily. For that reason, one should take more care and be sure that the wound presents an absolutely smooth surface from within the peritoneal cavity, so that the small bowel cannot become adherent to it. We have had within a year a patient very similar to this in whom the loop of ileum had become adherent to the stump of the appendix, which had not been infolded or invaginated into the cecal wall. That patient, even though he did not die so quickly as this one, did succumb while in the hospital and while an effort was being made to prepare him for operation. He drained an unusual amount of fluid from the Miller-Abbott tube, and it was never possible to hydrate him. It seems too bad that patients should lose their lives from something that can be prevented very easily if a careful surgical technic is used.

DR. HAROLD L. HIGGINS: It impresses me that these cases often carry on with minimal symptoms for two or three days after the initial vomiting. This child apparently was not sick enough for the attending physician to spot the fact that it was a case of intestinal obstruction. In one case that I saw recently, the doctor who cared for it got the impression it was merely so-called "intestinal flu."

DR. TRACY B. MALLORY: You were inclined, Dr. Farber, to assume that the obstruction at the start was intermittent and became permanent only shortly before exitus?

DR. FARBER: Yes.

## CASE 27322

### PRESENTATION OF CASE

*First Admission.* A forty-eight-year-old housewife entered the hospital complaining of frequent colds, sinusitis, easy fatigability and a chronic cough with small amounts of green sputum. She had also noticed a gain in weight.

Physical examination showed infected tonsils;

the blood pressure was 125 systolic, 80 diastolic. A tonsillectomy was performed, and the patient discharged one week later.

*Second Admission* (ten months later). The patient was admitted primarily for back strain following a fall a few days previously. In addition to chronic sinusitis, which still troubled her, she complained of occasional nausea and vomiting in the morning during spells of coughing and, in addition, a feeling of lethargy, sleepiness and anorexia.

In the previous five years, her periods had become irregular and scanty, and these symptoms were accompanied by hot flashes and an increasing nervousness. There had been a weight gain of 25 pounds in the previous two years, although presumably she had followed a 1200-calorie diet. For twenty-three years, the patient had been in the habit of drinking at least two cocktails before dinner each night. At no time had jaundice or tarry stools been noticed.

On examination, the patient was moderately obese and in no distress. The heart was normal, and fine rales were heard at the lung bases; the blood pressure was 150 systolic, 110 diastolic, the pulse 90 to 100. The liver was palpable four fingerbreadths below the costal margin, and a little tenderness was elicited on deep palpation. Slight tenderness was present over the lumbar spine and sacrum.

The urine showed a + test for albumin. The blood showed a red-cell count of 4,120,000 with a hemoglobin of 14.8 gm. (photoelectric-cell technic), and a white-cell count of 7100 with 52 per cent polymorphonuclears, 29 per cent lymphocytes and 19 per cent mononuclears. The sedimentation rate was 50 mm. in one hour; the nonprotein nitrogen was 17 mg. per 100 cc., the protein 7.0 gm., and the serum van den Bergh 2.2 mg., biphasic. A follicle-stimulating-hormone test was positive; the basal metabolic rate was +35 per cent; and a blood Hinton reaction was negative.

The patient was on a low-calorie diet, and two days after admission acetone was noticed on her breath. The urine then showed a +++ test for acetone and + test for bile; the blood sugar was 88 mg. per 100 cc. The diet was readjusted, and two days later both the acetone and bile had disappeared from the urine.

The patient was discharged on the fifth hospital day, with diagnoses of obesity, menopause, chronic bronchitis and sinusitis. Treatment consisted of a low-caloric, high-vitamin diet and endocrine preparations.

*Final Admission* (fifteen months later). In the interval between admissions, the patient had suffered from essentially the same symptoms as be-

fore — nervousness, lethargy and occasional nausea and vomiting. She was somewhat apprehensive, and her pulse ran between 110 and 120.

One week before admission, the patient suddenly developed a digestive upset, with malaise, nausea and vomiting, diarrhea and, finally, prostration. Her physician noticed that she was jaundiced and advised hospitalization.

The family and past histories were irrelevant.

On examination, the patient was listless and apathetic, but rational. Her skin was dry, hot, dehydrated and markedly jaundiced, with a mild telangiectasia of the hands and face. The heart was normal; moist rales were heard throughout the dependent parts of the left lung; the blood pressure was 90 systolic, 60 diastolic. The abdomen was distended, tense and tympanitic, with shifting dullness but normal peristalsis. Liver dullness reached the fifth interspace, and the organ could be felt on a level with the iliac crest in the mid-clavicular line.

The temperature was 97°F., the pulse 110, and the respirations 22.

The urine showed a ++ test for albumin, with a yellow sugar reaction and a ++ test for bile. The bile-stained sediment contained many hyaline and finely granular casts, a rare cellular cast and 50 white blood cells per high-power field. The blood showed a red-cell count of 1,590,000 with a hemoglobin of 65 per cent, and a white-cell count of 18,400 with 76 per cent polymorphonuclears. The nonprotein nitrogen of the blood serum was 15 mg. per 100 cc., the icteric index 50, a van den Bergh 10.9 mg. per 100 cc.; a brom-sulfalein test showed 100 per cent retention of the dye in the serum. The total serum protein was 6.9 gm. per 100 cc., the albumin being 3.5 gm., and the globulin 3.4 gm.

The patient was given a high-carbohydrate, high-vitamin, low-fat diet, with calcium gluconate by mouth and 25 per cent glucose solution intravenously. The course was rapidly downhill, and on the third hospital day the temperature was 104°F., the pulse 130, the respirations 40, and the blood pressure 128 systolic, 66 diastolic. The patient lapsed into coma, cyanosis appeared, and the jaundice intensified, although it was never extreme. Death occurred on the seventh hospital day.

#### DIFFERENTIAL DIAGNOSIS

DR. CHARLES L. SHORT: I think we can dismiss the first attack, which occurred two years before death. At least, I can find no clue there to the cause of death, although of course it is possible that the fatigue

may have been an early symptom of some underlying serious chronic disease.

At the second admission, fifteen months before death, the patient still had the nonspecific complaints of fatigue, nervousness and lethargy, some of which may be assigned to the oncoming menopause. In addition, she had anorexia and vomiting, which point to trouble in the digestive tract. The important diagnostic features at this admission seem to be the large and tender liver, the increased sedimentation rate and the subclinical jaundice, as shown by the van den Bergh test. I should think that the diagnosis of liver disease might at least have been entertained at this time, although there is no mention of it among her discharge diagnoses. I do not believe that we can overlook the increased basal metabolism although only one determination was done. I shall refer to that later.

In the hospital, she developed ketosis from a low-calorie diet. This seems an unusual development and perhaps points to a deficiency of glycogen storage in the liver. Furthermore, if liver disease was already present, this episode certainly was of no benefit to this organ.

On the third admission, the patient obviously had severe liver disease. Again there was an episode of starvation preceding the exacerbation of symptoms, which must have contributed further injury to an already damaged liver. She apparently had a severe anemia. Although the red-cell count was extremely low, the hemoglobin was 65 per cent, thus giving the amazing color index of 2. In the record, there is no description of the smear. At any rate, it seems to have been a hyperchromic anemia, which would go with liver disease.

DR. TRACY B. MALLORY: One smear is recorded: "Some of the red cells appear well filled with hemoglobin; others show considerable variation in size. Many red cells appear larger than normal, and rare stippled cells are present. There are 1 per cent young polymorphonuclears; otherwise the white cells are normal. The platelets are increased."

DR. SHORT: The patient had laboratory evidence at this final admission of severely upset liver function, with an altered albumin-globulin ratio. In spite of treatment, she died in about a week.

I think she obviously had primary or secondary liver disease. With the ascites and the rather rapid final decline, we can probably eliminate biliary obstruction, owing to gallstones or to neoplasm, as a cause of the liver damage. The increased metabolism and the rapid pulse suggest

hyperthyroidism. Decreased liver function has been described secondary to Graves's disease, but it would hardly be as severe as this, and there were no other diagnostic features of hyperthyroidism. There are two other conditions with increased metabolism in which the liver might be involved. These are malignant lymphoma and leukemia. There is no other evidence that I can see for lymphoma, and a leukemia at this stage would probably show some evidence of its presence in the peripheral blood. No bone-marrow studies, of course, were done. A monocytic leukemia might have produced this terminal picture, but I think we shall have to let the increased metabolism go as a single finding that was not confirmed. There is no positive evidence of primary or secondary neoplasia of the liver, although we cannot entirely rule it out.

We are left, then, with some type of hepatitis or cirrhosis. We have already decided against biliary cirrhosis. The facts that the patient was a woman and that there was a lack of pigmentation are against hemochromatosis. However, she did have glycosuria on the third admission, although this may have been due to therapy with intravenous glucose solution. One of the interesting features of this case is the size of the liver, although we know that the clinical estimate of the size of the liver is notoriously inaccurate. If the examiner was able to palpate the liver edge through a fatty abdominal wall and through the ascites, it certainly was a very large liver, with the edge down to the iliac crest. I think that this fact alone is against a toxic cirrhosis, with or without a final episode of acute liver-cell destruction. We ordinarily think of the liver in alcoholic cirrhosis as reduced in size, but this certainly is not always true. I do not believe that a liver even this large is against the diagnosis. This is especially true if the cirrhosis is in the stage, as I believe it may have been, of fatty infiltration, as described by Connor and Chaikoff,<sup>1</sup> rather than being markedly fibrotic. The patient had a history of a consistent intake of alcohol over many years, had been on a restricted diet, and at times had actually been starved. I shall make a final diagnosis, then, of alcoholic cirrhosis, probably in a stage in which fatty infiltration predominated.

DR. WYMAN RICHARDSON: I shall say cancer, if we accept the size of the liver as it is given here. A liver as big as this is *prima-facie* evidence of some form of neoplasm.

I think Dr. Short ought to know whether there was any bile in the stool. Do you know that?

DR. MALLORY: I cannot find a stool report.

#### CLINICAL DIAGNOSES

Cirrhosis of liver?

Ascites.

#### DR. SHORT'S DIAGNOSIS

Alcoholic cirrhosis of liver, in stage of fatty infiltration.

#### ANATOMICAL DIAGNOSES

Acute alcoholic cirrhosis.

Ascites.

Dermoid cyst of left ovary.

Obesity, slight.

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: This is a very alarming story, if one believes it literally, because the patient died of acute alcoholic cirrhosis beyond any shadow of doubt. The liver weighed 4000 gm.—even 5000 gm. is possible in such cases. It was bright yellow, owing chiefly to extensive fat deposit but also to some degree of intrahepatic bile stasis, and very finely granular but quite tough on section—a definite cirrhosis was already present. The liver cells showed the typical so-called “alcoholic hyalin” that one expects in such a case.

If one believes that two cocktails daily for twenty years were really responsible, I think we should all be greatly alarmed. However, we have some evidence, at any rate, that her statements were not entirely reliable. For instance, she swore that she adhered to a 1200-calorie diet, yet she gained over 30 pounds in a year. So that she may have cheated on the alcohol as she did on the food. We did make a few more inquiries afterward, and the results were suspicious although not actually positive: we discovered that gin was bought by the case, and we finally got an admission of at least a case a month. I am still not sure that is the whole story.

The cirrhosis had not advanced to a stage that produced any marked degree of portal congestion. The spleen weighed only 200 gm., scarcely enlarged at all. The amount of ascitic fluid was rather small—only a liter; it was probably due more to the change in level of the serum proteins, that is, the shift in the albumin-globulin ratio, than to the degree of portal congestion.

DR. SHORT: This is probably the first stage of portal cirrhosis?

DR. MALLORY: Yes. One not infrequently observes deaths in an even earlier stage. In large city hospitals and at the medical examiners' table, cases are frequently seen of deaths from acute hepatic insufficiency, showing large fatty

livers with no trace of cirrhosis. Such cases usually have stories not merely of extensive consumption of alcohol but also of virtual starvation so far as food intake is concerned. There is an interesting article by LeCount and Singer<sup>2</sup>—Dr. LeCount was medical examiner for Cook County for many years—on acute hepatic insufficiency as a cause of sudden death. They raised the question whether these deaths might be hypoglycemic, but had no direct proof of it. The livers were virtually devoid of glycogen at autopsy.

A PHYSICIAN: Was there any evidence of gastric hemorrhage?

DR. MALLORY: There was no history of gastric hemorrhage, so far as we know. There were no demonstrable varices. There was a dermoid cyst of the ovary, which had never been discovered.

a taste for hard liquor, and 95 per cent alcohol became popular as a beverage for the first time. Because of this, bathing alcohol and other forms of denatured alcohol were evolved for home use. As a beverage, 95 per cent alcohol was more hazardous than other alcoholic beverages because of its concentration; as its users became intoxicated they tended to be less careful about its dilution, and the death rate was high. With the repeal of Prohibition, the death rate increased to a still higher level, and there is ample police evidence to the effect that 95 per cent alcohol was, and still is, the responsible agent in a large percentage of cases.

Under the practice before Prohibition, the druggist who obtained a certificate of fitness from the Board of Registration in Pharmacy, for which he paid \$1.00 annually, was authorized to sell intoxicating liquors on the prescription of a physician, and could sell pure alcohol for mechanical, chemical and medicinal uses. The cost of a certificate of fitness has since been increased to \$5.00. With the revision of the laws following the repeal of Prohibition, the requirement that alcohol be sold for mechanical, chemical or medicinal purposes was withdrawn, although it is still sold by druggists with a label indicating this restriction on its uses. Basically, however, the druggist under present-day law is allowed to sell 95 per cent alcohol as a beverage at a cost of \$5.00 per annum for a certificate of fitness. This is special privilege indeed!

The danger of the return of the bootlegger if the privilege of the druggist were restricted is not serious. Massachusetts is the only state permitting the free sale of 95 per cent alcohol by druggists, and yet other states have not unduly suffered from bootleggers.

Finally, it is claimed that physicians would suffer if they were required to write prescriptions for 95 per cent alcohol. In the other forty-seven states there has been no objection on the part of the medical profession to this requirement. In New York, for example, physicians have not complained, and the death rate from alcoholism has been lowered in New York City since the repeal

of Prohibition, in contrast with the increased rate in Massachusetts, notably, in Boston.

If it is granted that the unrestricted sale of 95 per cent alcohol by retail druggists is a privilege, an assumption that the activities and letter of Mr. Silverman seem to bear out, it is difficult to rationalize how the unselfish efforts of physicians such as Dr. Leary and Dr. Moore to abolish, or at least to ameliorate, an indubitable public-health hazard should have received so little support from the legislators of Massachusetts.

---

## LOCAL HEALTH DEPARTMENTS

It is beginning to be apparent that local health departments, like most other divisions of human activity, cannot long stand still. Many formerly adequate health departments that tried to drift along have found themselves overtaken during the past decade: for example, one in the vicinity of Boston is now being administered by the head of the welfare department, for better or for worse. The fact that such officials have had no public-health or even scientific training does not disconcert them in the least—they can more glibly recite the incubation periods of communicable diseases than most physicians can. There has often been a gradual shift from physicians who may or may not have been good administrators to administrators who may or may not have been good physicians, and now are finding out that they need not have been physicians at all—just administrators.

The question of how much public-health authority can be safely taken over on a pure administrative basis could be debated at some length: professional and technical assistance is always available; sanitary ordinances are well codified; and the simpler types of milk-route epidemiology are now popularly understood. The public-health worker who rests entirely on these will soon find that he is in nonprofessional competition. A wholesome reaction to this static influence has been the production of well-conceived and well-written reports. A recent excellent example is the *Annual Report* of the Public Health Depart-

## SALE OF ALCOHOL IN MASSACHUSETTS

MR SAMUEL SILVERMAN's letter, appearing elsewhere in this issue of the *Journal*, criticizes a recent editorial, several of his objections and complaints seem to call for additional editorial comment.

The implication that Mr Silverman and his friends are better psychologists than Dr Moore and his associates is a matter of opinion and needs no discussion.

Mr Silverman claims that alcoholism is an unfair term to apply to those who use alcohol for beverage purposes and who suffer and die therefrom. It has been proved so many times that ethyl alcohol is the toxic agent in alcoholic beverages

which produce intoxication, sometimes with a fatal termination, that this question needs no discussion.

The letter asserts that the statistics and data contained in the former editorial are inaccurate and unfair. The statistics were obtained by Assistant Surgeon General Lawrence Kolb, of the United States Public Health Service, and are obviously authentic. The data with reference to arrests for alcoholism were furnished by the police departments of the respective cities shown, and the death rates by the health departments of the respective cities. Mr. Silverman's quarrel appears to be with a governmental agency and with the police and health departments of Baltimore, Boston, New York, Philadelphia and Washington.

It is said that the data used by Drs. Alexander, Moore and Leary, referring to deaths certified by medical examiners in Massachusetts as directly related to the ingestion of ethyl alcohol, are unwarranted. This attitude undoubtedly arises from the fact that Mr. Silverman, as mentioned above, does not recognize that alcohol, whether imbibed as whisky or as ethyl alcohol, is the toxic cause, directly or indirectly, of the deaths recorded. The proponents of the bill under discussion made no claim that 95 per cent alcohol, as sold by druggists, was the exclusive cause of these deaths.

Mr Silverman warns that restriction against the sale of 95 per cent alcohol by retail druggists would result in the return of the bootlegger and so forth. This acknowledges that the 95 per cent alcohol sold by druggists is used for beverage purposes. The intent of the law was that its use was to be limited to mechanical, chemical or medicinal purposes only, it was not to be used as a beverage.

To understand the situation which obtains with reference to the sale of 95 per cent alcohol by the druggist, a review of recent history is necessary. Before Prohibition, 95 per cent alcohol was used for alcohol baths, the sterilization of thermometers and other such purposes, it was not used as a beverage. Following the Prohibition Amendment, as bootlegging became organized, the smuggling of 95 per cent alcohol was found to be just as easy as that of beer and wine, and much more profitable. The American public developed

a taste for hard liquor, and 95 per cent alcohol became popular as a beverage for the first time. Because of this, bathing alcohol and other forms of denatured alcohol were evolved for home use. As a beverage, 95 per cent alcohol was more hazardous than other alcoholic beverages because of its concentration; as its users became intoxicated they tended to be less careful about its dilution, and the death rate was high. With the repeal of Prohibition, the death rate increased to a still higher level, and there is ample police evidence to the effect that 95 per cent alcohol was, and still is, the responsible agent in a large percentage of cases.

Under the practice before Prohibition, the druggist who obtained a certificate of fitness from the Board of Registration in Pharmacy, for which he paid \$1.00 annually, was authorized to sell intoxicating liquors on the prescription of a physician, and could sell pure alcohol for mechanical, chemical and medicinal uses. The cost of a certificate of fitness has since been increased to \$5.00. With the revision of the laws following the repeal of Prohibition, the requirement that alcohol be sold for mechanical, chemical or medicinal purposes was withdrawn, although it is still sold by druggists with a label indicating this restriction on its uses. Basically, however, the druggist under present-day law is allowed to sell 95 per cent alcohol as a beverage at a cost of \$5.00 per annum for a certificate of fitness. This is special privilege indeed!

The danger of the return of the bootlegger if the privilege of the druggist were restricted is not serious. Massachusetts is the only state permitting the free sale of 95 per cent alcohol by druggists, and yet other states have not unduly suffered from bootleggers.

Finally, it is claimed that physicians would suffer if they were required to write prescriptions for 95 per cent alcohol. In the other forty-seven states there has been no objection on the part of the medical profession to this requirement. In New York, for example, physicians have not complained, and the death rate from alcoholism has been lowered in New York City since the repeal

of Prohibition, in contrast with the increased rate in Massachusetts, notably, in Boston.

If it is granted that the unrestricted sale of 95 per cent alcohol by retail druggists is a privilege, an assumption that the activities and letter of Mr. Silverman seem to bear out, it is difficult to rationalize how the unselfish efforts of physicians such as Dr. Leary and Dr. Moore to abolish, or at least to ameliorate, an indubitable public-health hazard should have received so little support from the legislators of Massachusetts.

---

### LOCAL HEALTH DEPARTMENTS

It is beginning to be apparent that local health departments, like most other divisions of human activity, cannot long stand still. Many formerly adequate health departments that tried to drift along have found themselves overtaken during the past decade: for example, one in the vicinity of Boston is now being administered by the head of the welfare department, for better or for worse. The fact that such officials have had no public-health or even scientific training does not disconcert them in the least—they can more glibly recite the incubation periods of communicable diseases than most physicians can. There has often been a gradual shift from physicians who may or may not have been good administrators to administrators who may or may not have been good physicians, and now are finding out that they need not have been physicians at all—just administrators.

The question of how much public-health authority can be safely taken over on a pure administrative basis could be debated at some length: professional and technical assistance is always available; sanitary ordinances are well codified; and the simpler types of milk-route epidemiology are now popularly understood. The public-health worker who rests entirely on these will soon find that he is in nonprofessional competition. A wholesome reaction to this static influence has been the production of well-conceived and well-written reports. A recent excellent example is the *Annual Report* of the Public Health Depart-

From 1910 to 1925, he was head of Dr Young's Hospital, which was the only hospital in Arlington at the time he opened it. He was a member of the Massachusetts Medical Society and the American Medical Association.

A son, Dr Kenneth T. Young, a daughter and four grandchildren survive him.

## MISCELLANY

### PNEUMOTHORAX IN PATIENTS OVER FORTY

Of what value is pneumothorax in patients of middle age? Numerous studies of the results and complications attending artificial pneumothorax have been made, but these have nearly all been concerned with patients between the ages of fifteen and thirty-five. Our actual knowledge of the precise merits of pneumothorax in patients over forty is still meager. For that reason, a study (Diamond, S., and Ivey, H. T. Artificial pneumothorax in patients over forty. *Am Rev Tuberc* 43:475-490, 1941) made of World War veterans in whom pneumothorax was instituted merits attention. An abstract of their article follows:

A survey was made of 431 white World War veterans in whom pneumothorax was instituted or attempted after they had passed their fortieth birthday, during a five year period beginning January 1, 1935. Every one of the patients had a positive sputum and a roentgenographically demonstrable cavity at the inauguration of his collapse program. Eighty-one per cent had far advanced disease, 19 per cent had moderately advanced lesions. The disease process was unilateral in 49.3 and bilateral in 50.7 per cent. Fourteen per cent had at least one cavity whose diameter exceeded 4 cm. The average age was slightly under forty-four years—7 per cent were over fifty. The duration of the patients' tuberculosis prior to the attempted induction of pneumothorax ranged from one month to eighteen years.

Patients with apparently permanent closure of the cavities and conversion of the sputums were classed as successful, and these numbered 92, or 20.2 per cent. The unsuccessful numbered 487, and the impossible 311 per cent. The various complications of artificial pneumothorax occurred with no greater frequency than among younger patients. Death was due directly to the complications of pneumothorax in 5 patients. Sixteen of the patients who died had pure tuberculous empyemas, although it is difficult to estimate the degree in which the presence of intrapleural pus contributed to these deaths, for in all cases the pulmonary lesion was actively progressive. Including these 16 cases, the fatalities consequent to complications numbered only 21, or 4.9 per cent of the patients treated, which is about what may be expected in general.

The shorter the time the patient has been ill and the less extensive his lesion, the greater the chances for the success of the therapy and the smaller the probability of occurrence of empyema. Closure of the cavity is effected earlier in patients whose disease history has been brief although pleural effusions—a complication of little significance in most cases—are likelier to supervene in persons who have had tuberculosis only a short time.

The time interval of cavity closure and sputum conversion varies directly with the patient's age; most of the pneumothoraxes became successful in the latter half of

their first year. It seems advisable, therefore, to maintain pneumothoraxes of doubtful efficacy for a longer time in persons over forty than would be wise in younger patients.

Bilateral pneumothorax, properly administered in carefully selected cases, is well tolerated and ordinarily occasions no marked respiratory embarrassment. The surgical division of pleural adhesions is necessary to the completion of the collapse in a large number of persons in the fifth decade, just as it is in younger patients.

Weighing the results and the complications, the authors conclude that artificial pneumothorax is of distinct value in the treatment of patients over forty. It is not so effective as in younger persons, but neither is any other therapeutic measure. Thus far it appears that artificial pneumothorax is enduring in its effects in persons over forty, but final conclusions cannot be drawn until most or all patients in the successful group have been observed for a sufficient length of time after re-expansion to permit accurate estimation of the lasting effectiveness of their pneumothorax.—Reprinted from *Tuberculous Abstracts*, July, 1941.

### RESUME OF COMMUNICABLE DISEASES IN MASSACHUSETTS FOR JUNE, 1941

DISEASES	JUNE 1941	JUNE 1940	FIVE YEAR AVERAGE*
Anthrax	1	2	4
Chicken pox	11	81	10
Diphtheria	11	6	10
Dog bite	1302	1249	1383
Dysentery bacillary	14	11	17
German measles	535	64	211
Gonorrhea	302	297	304
Lobar pneumonia	207	225	78
Measles	3925	5722	3357
Meningococcus meningitis	16	1	8
Mumps	1114	641	43
Paratyphoid B fever	5	6	13
Scarlet fever	639	3	685
Syphilis	391	339	410
Tuberculosis pulmonary	297	229	291
Tuberculosis other forms	23	24	38
Typhoid fever	7	7	8
Undulant fever	7	3	3
Whooping cough	978	59	599

\*Based on figures for preceding five years.

#### GEOGRAPHICAL DISTRIBUTION OF CERTAIN DISEASES

Anterior poliomyelitis was reported from West Springfield, 1 total, 1.

Anthrax was reported from Peabody, 1, West Boylston, 1 total, 2.

Diphtheria was reported from Boston, 5, Fall River, 5, Frammingham, 1, total, 11.

Dysentery, amebic, was reported from Boston, 1, total, 1.

Dysentery, bacillary, was reported from Lynn, 12, Peabody, 1, Russell, 1, total, 14.

Infectious encephalitis was reported from Middleboro, 1, Wintertown, 1, total, 2.

Malaria was reported from Haverhill, 1, total, 1.

Meningococcal meningitis was reported from Boston, 1, Braintree, 1, Brockton, 1, Camp Edwards, 7, Fitchburg, 1, Northbridge, 1, Reading, 2, Weymouth, 1, Worcester, 1, total, 16.

Paratyphoid B fever was reported from Adams, 1, Beverly, 1, Lexington, 1, Salem, 1, Worcester, 1, total, 5.

Pellagra was reported from Boston, 1, total, 1.

Pfeiffer bacillus meningitis was reported from Lancaster, 1, total, 1.

Septic sore throat was reported from Beverly, 3, Boston, 1, total, 4.

ton, 6; Brockton, 1; Cambridge, 1; Fall River, 3; Fort Strong, 1; Newton, 1; total, 16.

Tetanus was reported from: Attleboro, 1; Hingham, 1; Methuen, 1; Quincy, 1; Worcester, 1; total, 5.

Trachoma was reported from: Boston, 1; total, 1.

Trichinosis was reported from: Camp Edwards, 11; total, 11.

Typhoid fever was reported from: Beverly, 1; Boston, 2; Fall River, 1; Haverhill, 2; Springfield, 1; total, 7.

Undulant fever was reported from: Arlington, 1; Lowell, 1; Norfolk, 1; Plymouth, 1; Shelburne, 1; Stockbridge, 1; West Brookfield, 1; total, 7.

Meningococcus meningitis was more prevalent than in any month since May, 1937.

Mumps showed a higher incidence than that in any June since 1936.

The incidence of undulant fever, although lower than that of the two previous months, is the highest for June since reporting began.

Chicken pox, German measles, measles and whooping cough were reported above the five-year averages.

Diphtheria, bacillary dysentery, pulmonary tuberculosis and typhoid fever were at normal levels.

Dog bite, gonorrhea, lobar pneumonia, paratyphoid B fever, scarlet fever and syphilis were reported below the five-year averages.

Only one case of anterior poliomyelitis was recorded during the month.

## CORRESPONDENCE

### "SALE OF ALCOHOL IN MASSACHUSETTS"

*To the Editor:* I am the "paid druggists' lobbyist" mentioned in the editorial appearing in the May 1 issue of the *Journal*, under the caption "Sale of Alcohol in Massachusetts," and I take no offense because of this title since Dr. Merrill Moore and others who were interested in securing the passage of the alcohol prohibition act also employed a lobbyist, but whether he was paid I do not know.

I believe your profession, which your journal reaches, ought to know all the facts pertaining to the attempt on the part of certain physicians to secure the repeal of the present law which permits retail druggists to sell alcohol for medicinal purposes. In the first place, may I state that from my conversations with many physicians I am satisfied that they do not agree with Dr. Moore and the others? Indeed, many psychiatrists are opposed to the position taken by Dr. Moore and the others with reference to the sale of alcohol by retail druggists. I know that Dr. Moore and other psychiatrists are tackling the problem of preventing death from alcoholism from the wrong end.

Psychiatrists are in agreement, I believe, that the question of alcoholism and its effect upon the individual is a personal problem and cannot be solved by a general attack. I am not a psychiatrist or even a physician, but I do believe that the question of treating those who suffer from alcoholism must be individual and not treated as a mass problem. However this may be, I do not believe that the statistics and data contained in the editorial and which were in the main submitted to the Massachusetts Legislature are accurate or even fair. In any event, the Committee on Legal Affairs of the Massachusetts Legislature and the Massachusetts Senate and House of Representatives did not agree with the statistics submitted, as both branches voted against a change in the present law.

I know that doctors will agree with me that "alcoholism" is an unfair term to apply solely to those who use alcohol for beverage purposes. Dr. Moore has very loosely used the statistics relating to alcoholism to apply to alcohol as such. His statistics as to the number of arrests and the number of deaths from alcoholism cannot by any stretch of the imagination be confined solely to alcohol, but undoubtedly refer to alcoholic beverages, which include whisky and other alcoholic beverages. To prevent a greater mortality or insanity from alcoholism, Dr. Moore should come out openly as a prohibitionist to prevent the sale, so far as possible, of all alcoholic beverages or else agree to confine the attack to the individual who suffers from alcoholism. The loose use of the word "alcoholism" by Dr. Moore and others to prevent the sale of alcohol by retail druggists was easily apparent to the members of the Legislature.

The statement accredited to Drs. Alexander, Moore and Leary "that 4505 deaths certified by medical examiners in Massachusetts from 1928 to 1938 were directly related to the ingestion of ethyl alcohol" is absolutely unwarranted and unfair because no one of these doctors has been able to certify that these deaths were directly related to the ingestion of ethyl alcohol as differentiated from other alcoholic beverages. In fact, before the legislative committee there was no defense made by Dr. Moore and the others to the proposition advanced that those patients who were charged with suffering from alcoholism were those who had taken alcohol as well as other alcoholic beverages, and that it was impossible to determine just what alcoholic beverage caused the death of the individual. The comparative statistics in the editorial indicating the number of arrests for intoxication in the various large cities of the United States are indeed misleading and unfair, because the number of arrests for intoxication always depends upon the policy of the police with reference to arrests. For example, in a city like New York very few arrests are made for intoxication because the policy of the police is not to bother with intoxicated persons other than to see to it that they are not harmed, while in other cities, like Boston, such persons are readily arrested. It is obvious that this factor must be considered in determining the number of inebriates, for no rational person will believe that in a given year, New York with a population of 7,000,000 people had only 112 arrests for intoxication, while a city like Boston with a population of approximately 790,000 had 5171 arrests for intoxication. The statistics are so absurd that any intelligent person can appreciate that important factors are missing.

Aside from all this, there is another important phase of the problem which Dr. Moore and his colleagues avoid. They do not answer the proposition that in Massachusetts the restriction against the sale of alcohol by retail druggists would inevitably result in the return of the bootlegger and the use of poisonous alcohol by those alcohol addicts who will be bound to secure their alcohol. So too, will it mean the return of witch hazel, Jamaica ginger, wood alcohol and other types of alcohol drinking, for if the retail druggist is denied the right to sell alcohol, the alcohol addict whom Dr. Moore talks about will resort to every means to secure his alcohol since there will be no avenue available to him because package stores do not sell alcohol. In other words, Dr. Moore would make the cure worse than the disease for the alcohol addict, while at the same time denying to honorable people the right to secure alcohol for medicinal purposes, of which there are many, unless the purchase were made in at least one gallon quantities.

Many physicians have stated to me that they do not want to be compelled to issue prescriptions for those who need alcohol for medicinal purposes, as it would result in a gratuitous service and a bothersome one. The medical profession is so thoroughly in disagreement on this whole proposition that it seems to me that before any attempt for this legislation is made by certain persons who, for reasons best known to themselves and which perhaps it is not necessary to discuss at this time, a more elaborate, substantial and accurate study should be made of the whole problem of alcoholism.

I have read many of the articles which have been quoted repeatedly by Dr Moore and Dr Leary and in most instances these articles refer to alcoholism and the use of intoxicating beverages, and not alcohol as such. We can not legislate morals into the people. That is an individual problem, and the sooner Dr Moore and the others approach this whole subject matter from that viewpoint, the sooner will progress be made.

SAMUEL SILVERMAN, *General counsel*  
Massachusetts State Pharmaceutical Association

11 Beacon Street  
Boston

## LICENSE SUSPENDED

To the Editor: The license of Dr Manford R. Spalding, 129 Central Street, Auburn, Massachusetts, was suspended by the Board of Registration in Medicine on July 11 because of deceit in the writing of narcotic prescriptions.

STEPHEN RUSHMORE, *Secretary*  
Board of Registration in Medicine

State House  
Boston

## BOOK REVIEWS

*Medical Genetics and Eugenics*. By Charles B. Davenport A.M., Ph.D., Clyde E. Keeler, M.A., M.S., Sc.D., Maude Slye, A.B., Sc.D. (hon.), and Madge Thurlow Macklin M.D., LL.D. 8", cloth, 141 pp., with 59 illustrations. Philadelphia: Woman's Medical College of Pennsylvania \$1.00.

The six lectures that comprise this book were delivered at the Woman's Medical College of Pennsylvania. These lectures try to show why a trained physician, as guardian of the public health, should have fuller knowledge of the genetic path by which man, the featherless biped who ordinarily talks, has come to his biochemical constitution.

Dr Davenport, the distinguished human geneticist, discusses in the first three lectures the subjects, Human Variability and Mate Selection, Some Social Applications of Eugenics, and, finally, 'Hereditary Relation to Medicine.' Dr Clyde E. Keeler takes up the question, 'The Value of Animal Experiments to the Understanding of Human Genetics,' in which he emphasizes the point that the identity of a great portion of our germ plasm is the secret of why physiologic experiments may be performed on normal dogs, cats, guinea pigs and rats and the findings of these experiments applied to normal man. Dr Maude Slye, in a lecture, 'Genetics and Cancer,' considers her own experimental evidence for the genetic control of the type, the site and the age of cancer. The last lecture, 'The Value of Medical Genetics to the Clinician,' by Dr Madge Thurlow Macklin, discusses actual cases that are of particular value to physicians in the diagnosis and therapy of relatively common conditions.

Throughout these lectures runs the plea for teaching more genetics to medical students and for the creation of an enlightened public opinion regarding genetics.

*Medicine and Health in New Zealand. A retrospect and a prospect*. By Douglas Robb, M.D., Ch.M., F.R.C.S. (Eng.) 8", cloth, 146 pp. Auckland, New Zealand: Whitcombe and Tombs, Limited, 1940. 8/6.

New Zealand seems to be particularly fitting as an experiment station for a social form of medicine. The experiment is already under way, for over three quarters of the hospital beds of all kinds are provided by the hospital boards of the Public Hospital System under the government. The chief weakness of the scheme at present, according to Dr Robb, is a lack of cohesion and correlation. There is no central control, which is essential to the orderly development of hospital work. No major changes have been made since 1910, even though the advance of medicine during the last thirty years should have made many changes imperative. This lack of adjustment to modern trends forms the basis of Robb's provocative book. A new survey of the whole situation is needed before any evaluation of the work of the past can be made or plans for the future laid out. This book contains much of interest for American readers, and no one in the field of social medicine should overlook it.

*The Medical Reports of John Y. Bassett, M.D. The Alabama student*. With an introduction by Daniel C. Elkin, M.D. 12", cloth, 62 pp., illustrated. Springfield, Illinois: Charles C. Thomas, 1940. \$1.50.

Dr John Y. Bassett, the 'Alabama Student' of Osler's delightful essay of nearly fifty years ago, whose fine portrait appears as a frontispiece of the published volume, described his experiences as a country doctor in Huntsville, Alabama, in the *Southern Medical Reports* (1849-1851). These volumes are now so rare that they have been reprinted, with an introduction by Professor Elkin. The story of Bassett's work and his letters from Paris, where he studied after his graduation, are too well known by physicians to need repeating. What is new and of great importance in this edition is an appended letter from Mastin to Osler, received after the *Alabama Student* was first published. In this correspondence, Mastin, who entered Bassett's office in Huntsville as a student of medicine, throws new light on Bassett and his career.

The book, a delightful imprint, sets a high standard for American medical publications. It is a choice item not to be missed by any physician or library.

*The American College of Physicians. Its first quarter century*. By William Gerry Morgan, M.D., LL.D., Sc.D., MACP. 4", cloth, 275 pp., with 36 illustrations. Philadelphia: American College of Physicians, 1940. \$2.00.

The American College of Physicians was founded in 1915 by Heinrich Stern, of New York, with a few physicians of that city. After Stern's death in 1918, the college fell into some disrepute, but reorganization soon took place on a sounder and more national basis. The headquarters were moved to Chicago. The organization grew rapidly. A journal—*The Annals of Medicine*, later called *The Annals of Clinical Medicine*—was established, but internal dissension was rising and friction again nearly wrecked the project. The college was reorganized for a second time, and headquarters were moved to Philadelphia in 1936. In 1940, there were over

4000 members, and it now contains most of the men recognized in the field of internal medicine.

This book, containing the history of the first twenty-five years of the American College of Physicians, is of considerable value as a record of the development of one of the outstanding medical groups in this country. In addition to the history, there are chapters on the constitution and bylaws, a financial record and a note on the publications by the college. The last part of the book is taken up with a chronology of the twenty-five years. The volume contains many small portraits in the text, but there is no list of members or index. The book is badly printed and is issued in the form commonly used by commercial catalogues. The lack of an index is inexcusable. The American College of Physicians is said to have been based on the Royal College of Physicians in London. Whatever the similarity, it is inconceivable that the older institution would have issued a history of its growth in a format so unfitting as this volume.

*Clinical Pellagra.* By Seale Harris, M.D., assisted by Seale Harris, Jr., M.D. With a foreword by E. V. McCollum, Ph.D., Sc.D., LL.D. 4°, cloth, 494 pp., with 66 illustrations, and 4 color plates. St. Louis: The C. V. Mosby Company, 1941. \$7.00.

This book is extremely valuable as an historical résumé of pellagra. It presents in an interesting and readable manner an account of the research done by workers at home and abroad. It is somewhat of an autobiography of the senior author, depicting his progress in the field of pellagra. His familiarity with the disease is graphically expressed throughout the book. His opinions are very frank and interesting, especially when he discusses the various theories of the etiology of the disease.

Attention is called to the environmental background that makes individuals prone to pellagra. Its relation to other diseases is briefly outlined, the discussions on sprue and pernicious anemia being particularly worth while. The chapter on treatment is excellent, outlining in detail the present-day therapy, with many satirical comments on the indiscriminate use of diets and vitamins. The advice on the patient's dietary regime commands attention. The chapter on prevention is admirable.

The book is of value to Northern physicians, especially in these days when there is a tremendous increase in the use of ethyl alcohol. They should become more conscious of pellagra, for there is no doubt that there are more cases in this climate than one realizes. The book on the whole can be profitably read by all physicians. The only comment that might be made by the reviewer is that there is too much repetition, and that the references, although instructive, could be broadened in their territorial scope.

*A Textbook of Clinical Neurology.* By J. M. Nielsen, M.D. 4°, cloth, 672 pp., with 179 illustrations. New York: Paul B. Hoeber, Incorporated, 1941. \$6.50.

This work is an attempt to present a short, complete review of neurology in one volume—an almost impossible task. The subject, like most specialties, has outgrown a single volume, and neurology has increased in the last twenty years beyond the realm of any individual specialist. No man can keep up with the modern literature; much less can he have the time to evaluate it. Kennier Wilson did so reasonably well up to 1935, but his book grew into two large volumes before his death, and some subjects

were incompletely covered. The one-volume, one-man textbook of neurology is probably a thing of the past, and Dr. Nielsen's fine book is an excellent example of the truth of this statement.

The book contains the usual introductory material, with charts similar to those found in many books. The standard diseases are described in the ordinary order, with illustrations of moderate value. What makes the book weak is the lack of evaluation of the literature, and even omissions of certain important additions in the last ten years. The reasons for these shortcomings are clearly stated above: an author cannot be blamed for not completing an impossible job.

For the reviewer, this book will not replace any textbook now at hand. One of the best sections is that on the organic diseases of the brain, which is illustrated by excellent photographs of pathologic sections, particularly gross sections. There is also an excellent chapter on clinical cerebral localization, and another, of less value, on vitamins and avitaminoses. For these sections, the book is of value to the specialist. For students or practitioners, it cannot be particularly recommended.

*Born That Way.* By Earl R. Carlson, M.D. 12°, cloth, 174 pp. New York: The John Day Company, 1941. \$1.75.

This is an unusually interesting biography of a doctor who was born of Swedish parents forty-four years ago. He suffered from a birth injury, which caused cerebral paralysis of the spastic type, with athetosis; awkwardness and stiffness of all four extremities resulted, making life extremely difficult for him from the very start. In spite of his handicap, he went through college and through Yale University School of Medicine, and has made a career for himself by teaching and training children who are similarly affected. He has a school on Long Island and another in Florida.

The book is a well-written story of a dramatic career, and his life illustrates what can be done through persistent effort in overcoming an almost insuperable handicap. It was not easy for him to enter any medical school, and it is greatly to the credit of his medical school that the dean saw in him a man of great promise. The whole world is indebted to him for the splendid example he has set, and for the work that he is doing in helping handicapped children.

*Wolf Child and Humau Child: Being a narrative interpretation of the life history of Kamala, the wolf girl, based on the diary account of a child who was reared by a wolf and who then lived for nine years in the Orphanage of Nidnapore, in the province of Bengal, India.* By Arnold Gesell, M.D. 4°, cloth, 107 pp. New York: Harper and Brothers, Publishers, 1941. \$2.00.

This unique account, based on a carefully kept diary of a missionary and his wife, the Reverend J. A. L. Singh and Mrs. Singh, should capture the attention of all readers interested in the age-old problem of Nature versus Nurture. Dr. Arnold Gesell, founder and director of the Yale University Clinic of Child Development, is of the opinion that this story gives ground for new faith in the stamina of human nature and the potentialities of human growth. There are ten instructive illustrations and a good chronology of Kamala's career as a closing chapter of the book. Students interested in the relations between heredity and environment will find it worth while to see that their libraries contain a copy of this book.

NUMBER 7

## THE POTENTIALITIES OF PREVENTIVE GERIATRICS\*

EDWARD J. STIEGLITZ, M.D.†

BETHESDA, MARYLAND

GERONTOLOGY is the science of aging. Geriatrics may be defined as that special field of medical practice dealing with disease in aged persons. The two must not be confused; the aged are the consequences of aging. The aged are people; aging is a process. Aging begins with the conception of a new individual and continues throughout life. Aging is a part of living, and thus involves both evolutionary and involutional phenomena. Senescence may be defined as that part of the aging process which occurs after the peak of development. Although the changes of senescence are largely involutional, it must not be assumed that all the consequences represent decline. There are important compensatory increments in certain functional capacities. Though long neglected, the unutilized potentialities of the aging and aged are worthy of serious consideration.

Just as geriatrics is concerned with the treatment of disease, preventive geriatrics is interested in the prevention of disease in later life. Probably the most significant period from the viewpoint of prophylactic geriatrics is the two decades from forty to sixty. It is in this period, or even before, that the involutional processes start, later to reveal themselves in the more obvious evidences of aging. Preventive geriatrics does not set as its objective the prevention of aging. To do that would be to arrest life. We cannot stop growing older. But we can hope to modify the consequences of aging and retard the progression of certain factors that make for premature senescence. Although aging is inevitable, the character of growing older is perhaps amenable to modification.

Why is the study of aging so young a science? Surely aging is no new phenomenon. It has continued since the beginning of Time. The age

of the earth has long interested geologists, the age of the universe has puzzled astronomers, and the age of man as a species has been the concern of anthropologists and archaeologists for many years. But the aging of *man as an individual* has received scant attention, and very little, indeed, is known about the basic mechanisms of aging as a biologic process. A young world is interested in youth. Mankind is slowly progressing toward maturation. As culture advances, we are commencing to realize the importance of the elderly.

Although the ancient Greeks delighted in the philosophic discussions of their aged seers, in those days the old were objects of curiosity because of their rarity. In Rome, Cicero wrote his famed *De Senectute* several years before his death at sixty-three. He considered himself an old man in the fifties, and justly so, for few of his contemporaries survived to such ripeness. The average life expectancy at birth for the Roman citizen was about twenty-three years, according to cautious estimates. During the next nineteen centuries, life expectancy increased very slowly. Data from New England in 1850 indicate that life expectancy at birth was but forty years. By 1900, this had risen to forty-eight years for the United States as a whole, and since then the rise has been dramatic. In 1930, life expectancy at birth had increased to about sixty years of age, and it is now over sixty-three for white members of the population.

Looking at the changing picture of humanity from another angle, one sees that in 1900 only 17 per cent of the total population of the United States were forty-five years or older. In 1940, 26.5 per cent were over forty-five, and conservative projection results in the estimate that in 1980—only another forty years hence—more than 40 per cent of the population will be over forty-five years old. Recently released figures from the 1940 census reveal that the median age of the population of this country increased from slightly more than twenty-six years in 1930 to just under twenty-nine years in 1940. This is an increase

\*The Delta Omega Lecture, delivered at the Massachusetts Institute of Technology, March 28, 1941. From the Unit on Gerontology, Division of Chemotherapy, National Institute of Health, United States Public Health Service.

†Visiting physician, Baltimore City Hospitals; consultant, National Institute of Health, United States Public Health Service.

of two and a half years of median age within a decade. At that rate, the median age of the population will be forty-four years in another half century. Furthermore, the number of persons aged sixty-five or more has increased from 6,633,805 to 8,956,206. This is a rise of 36.5 per cent among the elderly, as contrasted with a 7.2 per cent increase in the total population in the last decade.

Such figures speak for themselves. Gerontology is no longer merely academically interesting, but has become an urgent matter in the minds of those sufficiently farsighted to see the handwriting on the wall. The nation is aging rapidly. The virile, violent but short-lived days of physical pioneering are largely past. The future holds promise of profound change. A period of intellectual conquest may be dawning. Man at last lives long enough to have time to think.

The situation is wholly without precedent. Never before in the history of mankind has a like problem presented itself; there are no marked trails to follow. We are almost as ignorant of the potentialities of a maturer mankind as Columbus was of the vast future of this continent. As explorers, we can see but the fringe of a new era, a period fraught with undefined menaces, but likewise presenting vistas of delightful aspect. The children of today will be the elderly of tomorrow. It is our responsibility to explore so far as we are able, to light their way and warn them of dangers, so that this apparent boon of increased longevity does not become a curse. For great longevity without health is not only an individual tragedy, but may develop into a social evil viciously destructive to national economy. Contrariwise, increased longevity of the population can become an incalculably valuable asset to any commonwealth if the potentialities of the elderly are wisely guided.

Urgent and unanswered problems arise in economic, sociologic, political and psychiatric fields as well as in medicine. The direction of some of these problems is already indicated. The clamor of the aged for economic security is heard throughout the breadth of the land. The clamor will become louder. Fantastic schemes are advocated with fanatic vigor and have already taken on political flavor. The problem of employment of older men demands serious and immediate attention, for logic inexorably leads to the conclusion that either the increasing millions of elderly people must have opportunity to work and support themselves or the proportionately dwindling group of younger persons will have to support them in one way or another. One answer implies productivity suited to capacity, the other destructive

costs on what may ultimately become a minority.

Education, which is preparation, has not kept pace with these changes in the social order. Educational curriculums are still geared to the day when life expectancy was fifteen or twenty years less than it is today, when it sufficed that education prepare the boy or girl for the competition of adult life. Neither parents nor teachers have taken cognizance of the necessity for preparation for old age. It has been assumed with complacent smugness that the adult would learn how to grow old—gracefully, happily and usefully—without training or aid. Unfortunately, very few learn this spontaneously. The time has come when educators must revise their objectives. The accomplishments of such men as Oliver Wendell Holmes, William H. Welch, Goethe, Edison, Titian and many others in the evening of their lives are mere indicators of the vast storehouse of latent treasure in those so often sneeringly dubbed "old men." Such careers are rarely fortuitous. Continued development is greatly enhanced by cultivation.

The remarkable increase in life expectancy is attributable largely to control of infectious diseases in childhood and early adult life. This has been accomplished chiefly by the public-health officer and the pediatrician. Through the institution and maintenance of modern sanitation, infant mortality has been dramatically reduced. So-called "summer complaint" was a dreaded disorder of infants that only the older ones among us remember. It passed with the disappearance of contaminated milk and water. Typhoid fever not so many years ago filled the wards of the hospitals in our major cities. Today, it is difficult to find sufficient cases for the teaching of medical students. Cholera, plague, smallpox, diphtheria and scarlet fever are under control through quarantine and immunization. Today, an epidemic of any of these diseases would bring about an immediate condemnation of the health department of the afflicted community. The maintenance of such safety is dependent on unrelaxing vigilance and constant educational activity. The daily hygiene and the nutrition of the people likewise improve under the guidance of continuous dissemination of the knowledge gained by research.

Prophylactic pediatrics has contributed greatly to increasing life expectancy. Not only has there been a vast improvement in the curative therapy of pediatric disease, but the pediatricians have done more than any other group of physicians to advocate and apply individual preventive medicine. By better feeding of presumably healthy ba-

bies and by prophylactic immunization, they have made healthy children healthier. The pediatrician has recognized that health is more than the mere absence of disease, that there are degrees of health. Such prophylactic practices have not only reduced infant and juvenile mortality, but have also unquestionably prevented many chronic sequelae from childhood ills. It is worthy of emphasis to note that marked advances in pediatric knowledge followed recognition of the fundamental concept that the child is not merely "the little man," but presents nutritional, immunologic, functional and structural problems and characteristics peculiar to infancy or childhood or both. A similar focus of attention in connection with senescence presents quite different problems because of specific, though ill understood and less appreciated, structural and functional differences. Thus geriatrics, or the care of the aged, becomes dependent on gerontology, the science of aging.

\* \* \*

Before discussing the application and potentialities of preventive geriatrics, it might be well to orient the problems of gerontology, which are logically divisible into three major categories.

The first is the biology of senescence as a process. Aging is a part of living. The basic biologic processes involve all different forms of life, and should therefore be amenable to study by many disciplines. It must be admitted that ignorance of this subject is profound. Unanswered as yet are such fundamental questions as just what happens to a cell with aging, why aging occurs, what accelerates or retards it, what mechanisms are involved, and why. The elucidation of these basic questions may solve many riddles, among them the riddle of cancer and perhaps that of arteriosclerosis. Scientifically, the cancer problem is but a subdivision of the larger question of aging.

The second category includes the clinical problems of senescence in man, which are clearly divisible into those relating to normal and to abnormal senescence, the latter conditioned by the disorders associated with advancing years.

Normal aging brings many changes, some obvious, others obscure, but all insidious and inevitably progressive. Structural alterations, psychologic changes and biochemical and physiologic differences arise. Normal is not a fixed point but a series of variables that change with age. Chronologic age, as measured in years and months, is not identical with biologic age. Physiologic age varies with each person. The greater the duration of life, the greater the variation. Furthermore, no one ages uniformly throughout, for dif-

ferent structures and systems age at different rates at various times in the life span. At certain ages, the involution of certain structures apparently becomes accelerated. This is illustrated by the rapid thymic involution in infancy and by the quickened regression of the generative organs at the climacteric. Mental aging likewise reveals much individual variation. Because of the complex relation, no single criterion of physiologic age can ever prove feasible.

There is a common misconception that senescence implies decline alone. This is distinctly an erroneous concept, for there is considerable compensatory enhancement of certain functional capacities. For example, loss of physical strength and speed of reaction are often counterbalanced by increased skill and judgment. It has been said that the older mind does not learn readily. The popular phrase, "You can't teach an old dog new tricks," has done immeasurable harm, for it has become so fixed in the minds of young and old alike that its validity is assumed. As a result, many older people admit defeat before trying, and opportunities for adult education are suppressed. Recent and comprehensive studies reveal that once this adult resistance to learning is overcome, the capacity to learn is but very slightly diminished by aging. There is some slowing of the rate but an increase in thoroughness. It would be better to reiterate "It is never too late to learn."

There are many disorders the frequency of which rises sharply with advancing years. The distinctions between the changes of normal senescence and certain of these so-called "degenerative disorders" are not sharply defined. It is most difficult to distinguish certain phenomena of disease from those attributable to aging. The phenomena of disease are, after all, exaggerations of normal reactions and do not imply new mechanisms.

The most significant of these geriatric disorders are cardiovascular renal disease, arthritis, diabetes mellitus, gout, cancer and certain syndromes of the climacteric. Of these, the cardiovascular group, including hypertensive arterial disease and arteriosclerosis, is by far the most significant. Arthritis exacts an immense toll of disability, although its mortality is low. A glance at mortality tables reveals that these diseases so frequent in the latter half of life are replacing tuberculosis, accidents, diarrhea and enteritis as the leading causes of death.

Two characteristics common to all these geriatric disorders are of special concern. First, acute infection plays a negligible role in their etiology. Although chronic foci of infection have long been incriminated as contributing

to the causation of arthritis and play a part in the pathogenesis of certain circulatory and renal diseases, none of these disorders can be classified as infectious or communicable. Secondly, all are chronic and progressive, and usually insidious of onset. The progression is often slow, but it is, nevertheless, inevitably persistent. None are self-limited diseases tending toward spontaneous cure and followed by a protracted period of lowered vulnerability. Rather does the progression of these disorders continuously increase vulnerability to exacerbation and accelerated decline. Cure is, at present, largely beyond hope. The best therapeutics cannot cure hypertensive disease, diabetes, gout or chronic arthritis. Control and retardation of progression are, however, feasible. The adequately controlled diabetic patient is vigorous, active, useful and productive despite the fact that he still has the disease. The earlier in the course of these diseases control measures are instituted, the more effective is the therapy. More can be accomplished with the aging than for the aged.

The problems presented to preventive medicine in the later decades of life differ radically from those encountered with younger age groups. These disorders are not amenable to mass prevention as infectious diseases are. They are not contagious. They are progressive. Thus, preventive geriatrics must become individualized, and it must be applied almost continuously. We cannot immunize a person against hypertensive disease and advise that he report again in two years for revaccination. Furthermore, each case of hypertension requires different therapy for control. No two cases are alike. Individualization must be the keystone of the arch of personal preventive medicine. The control of these maladies requires a totally different approach, and sooner or later these problems will absorb a great part of the time and energies of health officer and practitioner.

The third category concerns the socioeconomic problems introduced by increased longevity, greater life expectancy and the rising median age of the population; they are immense and extremely complex. Industry is just awakening to the implications of the fact that the average age of employees is increasing at a surprising rate. This has been occurring despite the fact that until very recently the vast numbers of unemployed permitted and encouraged the selection of younger workers. In the present emergency, the shortage of trained personnel for technical jobs and the deviation of young men into military training will accelerate the rise in the average age of industrial

workers. War would further speed this rise. Problems of placement, retirement, the utilization and conservation of the health of older men in key positions of great responsibility, the complexities of workmen's compensation laws in relation to occupational exacerbation of pre-existent disease and many more questions are becoming increasingly urgent. Certain problems of adult education have already been mentioned. Problems involving social attitudes toward the aged are distinctly pertinent.

These three major divisions of the problems of gerontology are intimately inter-related. Advance in any one field depends on parallel or preceding advance in the other categories. It cannot be over-emphasized that the more we know about the fundamental biologic mechanisms of aging, the more effectively can clinical medicine treat and understand the aged and aging. Likewise, the greater the clinical knowledge concerning the changing capacities and limitations of older people, the more intelligently can the serious and complex socioeconomic problems be considered. Knowledge, gained by painstaking, tireless and honest research, is the foundation of progress.

\* \* \*

The question arises whether preventive geriatrics is a public-health problem at all. If guardianship of the health of the nation is the function of public-health services, all preventive medicine logically falls within the scope of our responsibilities. As previously suggested, preventive medicine is of two types. These may be called the impersonal or "wholesale" type and the individual or "retail" form of prophylaxis.

Impersonal public-health activities have included the institution and control of modern sanitation, the enactment and enforcement of both local and national quarantine regulations, the control of avoidable hazards of atmospheric contamination and of the physical environment in industry and in schools, public buildings and homes, educational activities in schools and elsewhere directed toward the control of communicable diseases and, last, but not least, the encouragement and application of mass immunization against certain infective diseases. These methods have resulted in magnificent improvement in the health of our youth. However, it is notable that although life expectancy at birth increased fourteen years in the quarter of a century from 1910 to 1935, life expectancy at fifty years increased less than three years. There is reason to pause and consider why the gains have been so asymmetric.

Personal preventive medicine, on the other hand, requires individualized handling of health prob-

lems. Such health-maintenance activities are illustrated by the better student-health services and periodic examinations in industry and to a more limited degree by practitioners of medicine. Included in programs of individual health maintenance must be provision for therapy to control in their incipency the progressive disorders of later life. There are four types of therapy, but we have descriptive adjectives for only three of them: prophylactic therapy, curative therapy and palliative therapy. The fourth is that form of treatment intended to control noncurable disorders and retard their progression. We might temporarily call it "controlative" or "retardive" therapy for want of a better term.

Both these approaches toward health maintenance have their limitations. Impersonal preventive medicine, which has been the mainstay of public-health work in the past, is limited in its effectiveness almost solely to infective and communicable diseases. It is applicable only to groups with a community of interest. It is feasible only with relatively homogenous groups in which a minimum of individualization is requisite. Mass production is effective only so long as the units dealt with are identical or nearly so. With increasing age, individual variability increases. Individuality is a composite of intrinsic and inherited characteristics as modified by the accumulated experiences and vicissitudes of existence. As we age, we each acquire a highly personal set of experiences, mental actions, reactions, infections and intoxications. The greater the age, the greater the variability between individuals.

The limitations of personal preventive medicine as applied to older persons are quite different. In the first place, a great deal of time is required for proper individualization. The early detection of chronic and progressive disorders is more difficult and time consuming than the diagnosis of frank acute disease. The disorders met with in older people are usually asymptomatic in their incipency, when most can be accomplished therapeutically. Frequently, extensive diagnostic and functional studies are necessary to reveal occult defects, which are, nevertheless, significant, for they are often precursors to extensive impairment of health. Furthermore, to prevent, control or retard these disorders, frequent consultations for observation and guidance are necessary. Such work cannot be hurried and requires the highest type of diagnostic acumen. Thus, the practice of individual prophylactic geriatrics is of necessity relatively expensive.

Another and severe limitation to the effectiveness of individual preventive medicine lies in man-

kind's curious perversity in declining to make prophylactic efforts on his own behalf. The best advice is relatively useless if not followed. Impersonal preventive medicine deals largely with matters that require little or no effort on the part of the recipient of the benefits. The city dweller has his sanitary milk and water, his clean food and his protection against communicable diseases without directly participating in the work necessary to ensure these blessings. Personal efforts, often of considerable degree and sometimes involving irksome restrictions, are absolutely essential in the management of early degenerative disorders to retard their progression. Unlike the majority of infectious and acute diseases, chronic disease is not infrequently etiologically associated with indulgence. This is particularly notable in diabetes mellitus, obesity and certain forms of vascular disease.

Another difficulty arises from the fact that although new curative methods of treatment are immediately taken up by both physicians and the lay public, prevention of disease is not regarded as a matter of urgency, and adoption is therefore slow. Geriatric disorders, being insidious and painless in their beginning, are usually neglected; those diseases that hurt early receive prompt attention. With chronic progressive disorders, the patient usually waits until the damage is irreparable, and then expects, nay even demands, that the physician casually shake a miracle from his sleeve. This occurs with such tragic frequency that the physician begins to wonder if pampering paternalism has not erased from the public consciousness the recognition that responsibility for health rests first and foremost on the individual.

Prevention lacks the drama of cure. It is axiomatic that volunteered or free advice is almost never followed. Advice must be sought to be used, and should be paid for if one expects conscientious application. Price as a criterion of value is a misconception that cannot be eradicated in less than several generations. It is extremely difficult to sell prophylaxis. The benefits are revealed only statistically. Statistics are abstractions and thus have very little appeal to the emotions of egocentric mankind. One cannot say, "Do not cross railroad tracks without looking, for you will surely be hit by a train the first time you try it." This is not true. One can say, however, "You will probably live to cross more railroad tracks if you always stop, look and listen. Those who do not, take chances." But those who prefer to take chances, to gamble rather than make an effort, are in the majority.

The greatest obstacle to effective preventive geri-

atics is this inertia. It is not, however, an insurmountable obstruction. Vaccination was introduced against violent agitation. Even today there is much passive and some active resistance to many procedures of preventive medicine. Education is gradually diminishing this resistance, and has often caused parents to seek prophylactic immunization for their children. But education is not accomplished overnight. The course in education to overcome the general inertia of adults toward personal preventive medicine will be a long and arduous program. The deeply ingrained tendency to hear only what we want to hear and see only what we want to see must be combated continuously. And such education must start with the physician, not only as teacher but as student as well. Physicians are proverbially neglectful of their own health and notoriously unmindful of the potentialities of prophylaxis. Let it never be forgotten that example is the first principle of successful pedagogy!

\* \* \*

With the indication why impersonal or community approaches to health maintenance are inadequate to stem the rising tide of disability due to chronic disease among aging adults, the question arises what can be done to facilitate the application of individual prophylactic medicine or preventive geriatrics. Education is the primary step. It is essential that every opportunity be grasped to reiterate and emphasize that health is more than the mere absence of disease. Health has quantitative attributes. Few, indeed, are those who are truly and fully healthy. Physical and mental fitness are not static. Health involves reserves of functional capacities in excess of daily requirements and adaptability to shifting burdens.

The measurement of physical health is fraught with difficulty. Thus far, no one has formulated an adequate minimum routine of examination to reveal the degree of health. Unquestionably, many of our criteria of normality are unsuitable, for there has been but little consideration of age as a variable. The changes of age affect the criteria of health. Arbitrary standards based on chronologic age do not suffice, for biologic age is not necessarily the same as chronologic age. The greater the duration of life, the wider will be the fluctuations between physiologic and chronologic age. The question of how physiologic age may be measured is perhaps the most urgent of all the clinical problems of gerontology. The physician applies that indefinable something we call clinical judgment and arrives at an approximate estimate. There is little precision in such evaluations, however. A logical approach to quan-

titation of biologic age is through the measurement of several functional reserve capacities. Study of several is necessary, for aging does not proceed uniformly throughout the individual. Depletion of reserves occurs long before actual functional failure, when subjective symptoms arise. Such depreciation of reserves is detectable only by the application of controlled stress procedures eliciting responses to increased physiologic work as part of the health inventory. For example, it takes a steep climb to reveal the weak spots of an automobile engine or of an apparently healthy heart. No single observation of normal findings on physical examination can reveal how the body will react under conditions of stress. The pulse rate may be normal at rest, but may rise to excessive heights on effort; the blood pressure may be within normal limits during calm conversation, but may soar to dangerous levels with anger or fear.

Periodic health inventory is the foundation for personal preventive medicine. The term "inventory" is used advisedly, for it is far more comprehensive than the more commonly employed term "examination." The average layman expects an examination to be completed in about half an hour. An adequate health inventory requires much, much longer. A careful, painstakingly detailed history is important. The details of the past are of accumulative value to the physician. Personality plays a major role in personal hygiene for health maintenance. Information gained from laboratory procedures, x-ray studies and functional tests is accumulated and correlated with the other observations. Then, and only then, can the physician evaluate the degree of health of an individual patient. These data make possible the formulation of sound and considered recommendations. It is the prophylactic advice that determines the value of periodic health audits. It is of little profit to the patient if the physician merely records his observations on the card and does not amplify his remarks. Because of this and also because many such inventories are carelessly and superficially conducted, the periodic examination has fallen into disrepute in many quarters. There is no weakness in the principle, but the methods of application have frequently been woefully poor. All too often, the doctor remarks that the patient appears a little "run down" and prescribes a "tonic." This may be equivalent to whipping or spurring a tired horse. To be sure, it makes him go faster for a time, but it hardly helps the horse. The only effective remedy for fatigue is rest.

Rest, to be effective, requires time. Time is a vitally important element to all those concerned with geriatrics. In the first place, time is obviously a factor in aging per se. Secondly, repara-

tive processes are slow, and much more time is required to accomplish the same degree of physical rehabilitation in older persons than in children. Clinical experience shows that a man of fifty may require ten times as long to recuperate fully from an acute infection as a child of five. Therefore, convalescence must be prolonged in proportion to age. The human body has a liberal credit structure on which it may draw in periods of emergency. Violent exertion may lead to an oxygen deficit, which may require some little time for repayment when hyperpnea is continued after the cessation of exertion. Likewise, one may "burn" against the future by "running on one's nerve," by using stimulating drugs, such as caffeine, or by ignoring the warnings of fatigue. Such borrowing is against the tissue reserves of energy and fuel. Sooner or later, these debts must always be paid. With aging, credit gets tighter. Not only is there less margin, but the call for payment becomes more urgent. Fatigue comes on more readily, and more quickly turns into exhaustion. It is increasingly imperative, therefore, that the warnings of fatigue be heeded as we grow older. Preventive geriatric advice should include emphasis on the importance of slowing the pace, avoiding overfatigue and taking sufficient time for recuperation. Thus, the final reckoning may be postponed.

Adequate prophylactic counsel must include many aspects of the patient's life and daily hygiene. The mode of living, adequacy of sleep, character of work, forms and amount of exercise, extent of relaxation and investment of leisure all play parts in the hygiene of health. Careful consideration of the habitual dietary is essential. With older people, the questions of bulk, vitamin intake and fluid balance are particularly pertinent. It is curious how often water is forgotten in considering dietary imbalances. Psychic factors must not be ignored. Many unnecessary anxieties are associated with both the masculine and feminine climacteric, and many avoidable psychic traumas from family attitudes toward the aged may be prevented by timely explanation. Conflicts due to competition with youth at work are frequently benefited by simple airing.

Aging accentuates idiosyncrasies, and certain fads may become ingrained convictions. So long as these dietary or other fads do no harm, it is wisest to leave them alone. The aged person knows quite well what he or she cannot tolerate in the way of specific food aversions. The keynote of all advice to the healthy aging or aged patient is: moderation in all things—in work, play, exertion, food and drink. Much mischief

may be done by sudden and radical curtailment of such habits as the use of tobacco, alcohol or coffee.

If a careful health inventory reveals the beginnings of disease, active therapy should be instituted promptly. As previously mentioned, it is a characteristic of the diseases of late maturity that they are progressive. The earlier retardive or controlative management is applied and the more continuous is the guidance, the better are the results. Although delay in instituting proper therapy on the discovery of an early case of diabetes or hypertensive arterial disease is less likely to have tragic consequences than the neglect of an early case of cancer, this fact never justifies postponement of therapeutic measures. Procrastination permits the degenerative changes to progress to the point where treatment becomes ineffective. It is beyond the scope of the present discussion to consider the principles of active treatment in geriatric medicine.

\* \* \*

There is much that public-health services can do to forward preventive geriatrics. Education of the adult population in the importance of prevention, control and retardation of the chronic and progressively disabling diseases of later life will encourage the seeking of such periodic inventories as those just described. If people request these and are aware of the necessity for comprehensive thoroughness, the services will become available. Today, it is often extremely difficult, even in the larger cities, to find physicians whose primary interest is to maintain health rather than treat disease. Pediatricians are the exception. Yet it is clear that such personal preventive medicine is necessary if we hope to check the ever-increasing numbers of middle-aged and elderly people partially or totally disabled by chronic illness. The economic burden of chronic illness is already a staggering fraction of the total losses due to ill health. Mental disability requiring institutional care must be included in these considerations. It is noteworthy that admissions to state hospitals for mental disease due to cerebral arteriosclerosis jumped in the last twenty-five years from 7.7 to 49 per 100,000 population over forty years of age; this is an increase of over 500 per cent.

Industry is much concerned with these questions, and industrial medicine is in a particularly advantageous position to advance preventive geriatrics. To emphasize the value of adult preventive medicine, it is necessary only to mention that sickness absenteeism of nonindustrial origin is responsible for about twenty times as much lost time as industrial injuries of all sorts. Not only do industrial physicians have the oppor-

tunity to examine hundreds of thousands of new employees each year but also they have the invaluable privilege of examining these same men and women at periodic intervals for many years. The factory stands in much the same relation to many adults as the school holds in relation to children. The role of the school physician and school nurse in developing prophylactic pediatrics was and is most significant. A similar opportunity to develop and apply prophylactic geriatrics awaits industrial physicians and nurses. Divisions of industrial hygiene in health departments can do much to encourage the expansion of such activities. Prophylactic geriatrics does not start at any particular age; health in maturity is good insurance toward healthy old age.

There remains for brief discussion the greatest and most important service that public health can offer the older fraction of the population: research into the problems of aging. Here the field is so wide, so untrammled and so unexplored that the potentialities are truly without end. I have deplored our ignorance of the fundamental biologic process of senescence. Badly needed are accurate and controlled studies to reveal what actually happens with aging. Cytologic, biochemical and physiologic definition of the changes that are part of normal aging are necessary as base lines on which to place evaluation of what constitutes "normal" in relation to age. The relations of age to growth and growth potentials, the changing vulnerability of cells to noxa and to pharmacologically active substances urgently require illumination. Nutritional requirements and tissue respiration in relation to age are fertile fields for study, and are ready for cultivation. The etiology and pathogenesis of arteriosclerosis, hypertensive arterial disease and cancer have obvious but ill-defined relations to the aging process.

Clinical researches are needed just as urgently. Only a few of the many unanswered questions clamoring for solution are the problems of how to evaluate physiologic age in man, and the definition of the curves of "normal" in relation to age. Such knowledge is prerequisite to studies of most geriatric diseases. Present clinical methods of functional mensuration need critical appraisal, and new, more precisely controlled, stress-test procedures are wanted. Any advance in knowledge concerning the so-called "degenerative diseases"

advances geriatrics, but we must not forget the lesson learned from pediatrics, namely, that the greatest advances were made when the peculiar structural, biochemical and physiologic characteristics of the infant and child became more clearly defined.

The socioeconomic problems of the aging population are not beyond the ken of public health. The problems of industrial health, housing, optimum nutrition and old-age assistance and the costs of chronic illness, chronic-disease hospitals and the maintaining of mental health are all borderline questions.

\* \* \*

In brief recapitulation, it should be emphasized that the three major categories of problems, the biology of senescence, the clinical questions of aging man and the socioeconomic problems, are all intimately related. Advance in one field will be immediately reflected by progress in the others. The more we know concerning the fundamental processes of aging, the more effective can clinical geriatrics become; the more precisely clinical medicine can define the changes in capacities and limitation that occur with normal aging and the more effectively it can apply preventive geriatrics, the more intelligently can the socioeconomic problems be attacked. These three divisions cannot be arbitrarily separated. Comprehensive programs of research must consider the field as a whole.

Prophylactic geriatrics does not take as its primary objective the prolongation of life. Rather, in the words of George Morris Piersol, does it aim to "add more life to the years rather than more years to life." By understanding and developing the capacities of older persons, it can help them to remain useful much longer. There is no greater tragedy for the aged than the sense of uselessness that society today prematurely imposes on them.

It must not be forgotten that the posts of greatest responsibility, requiring the highest judgment, technical training and wisdom, are held by older men. And with good reason. The accumulated judgment and wisdom of these older minds represent one of the most valuable and potent resources of the nation. The conservation of the health and vigor of these almost irreplaceable older men is a major potentiality of preventive geriatrics.

# CERTAIN OBSERVATIONS IN LOW-NITROGEN, NORMAL-OXYGEN ATMOSPHERES RELATED TO THE PROBLEMS OF HIGH-ALTITUDE FLYING\*

ALLAN M. BUTLER, M.D.,† JAMES L. WILSON, M.D.,‡ CLEMENT A. SMITH, M.D.,§  
AND SIDNEY FARBER, M.D.¶

BOSTON

IN the course of studying the effect of low-nitrogen, normal-oxygen atmospheres on the dyspnea of obstructed breathing,<sup>1</sup> observations were made on the effects produced by such atmospheres that bear directly on the problems of high altitude flying. Because these effects have become of particular importance in current aerial warfare and in low atmospheric-pressure experiments pertaining thereto, publication of our findings seems desirable.

The experiments were conducted in a steel chamber,<sup>||</sup> which consisted of two rooms. In each room, controls by suitable pipes and valves were made so that from either inside or outside the pressure chamber the room could be evacuated rapidly and almost noiselessly by means of a steam ejector to any desired extent and could be refilled with room air or oxygen as desired. A bank of oxygen tanks was provided with a reduction valve so that an adequate source of oxygen at a pressure of 50 to 100 pounds was available. Cooling of the chamber was effected by a coil carrying brine. The accumulation of carbon dioxide was prevented by frequent small reductions of total pressure and additions of oxygen and air. Convection currents facilitated the absorption of carbon dioxide by a container of soda lime. Water pipes to each chamber provided the essential fire-extinguishing equipment.

By repeating the process of alternately lowering the total atmospheric pressure until the partial pressure of oxygen was reduced to approximately 125 mm of mercury and then increasing the partial pressure of oxygen to approximately 225 mm, a total atmospheric pressure of 200 mm (corresponding to an altitude of approximately 32,000 feet) and a partial oxygen pressure of 155 mm

could be provided within the chamber in ten minutes. A fairly accurate account of the oxygen pressure was kept by calculation from the pressure changes. An accurate check was made at intervals by direct oxygen analysis, which took but two or three minutes.

From observations during experiments at low-nitrogen, normal-oxygen atmospheres, Mosso,<sup>2</sup> Winterstein,<sup>3</sup> Fegler<sup>4</sup> and Dill, Edwards and Robinson<sup>5</sup> postulated an excess carbon dioxide elimination that was not dependent on the hyperpnea of anoxemia. Ruhl<sup>6</sup> found that the slight lowering of the carbonic acid of arterial blood in such atmospheres was accompanied by a compensatory de-

||The plan of the chamber was conceived by Dr. James L. Wilson. Its construction was supervised by Dr. Wilson and Professor Philip Drinker of the Harvard School of Public Health.

bon dioxide pressures over this range in altitude does not indicate an abnormal elimination of carbon dioxide. That there was no significant alkalosis due to abnormal loss of carbonic acid from the blood is indicated by the fact that there was no increase in urine volume or alkalinity such as would accompany a respiratory alkalosis.<sup>8</sup> Thus our results do not indicate that in rarefied atmospheres there is a significantly increased elimination of carbon dioxide that is independent of the hyperpnea of anoxemia.

Fegler<sup>4</sup> and Dill and his co-workers<sup>5</sup> believed that the greater elimination of carbon dioxide observed by them at low pressures resulted from the greater diffusion of carbon dioxide from the alveolar spaces to the pulmonary dead space when the air in the lungs was reduced in density. It has

FIGURE 1.

*This chart shows the rates of diffusion of oxygen into a spirometer at a constant partial oxygen pressure of 150 mm. of mercury at total atmospheric pressures of 760 mm. of mercury (open circles) and of 300 mm. of mercury (solid circles).*

similarly been suggested<sup>9</sup> that an acceleration of the diffusion rate of oxygen at low-nitrogen pressures facilitates respiration. To obtain data on the diffusion of oxygen at atmospheres of varying density, a large spirometer was filled with nitrogen after the oxygen of the dead air space of the apparatus had been washed out with nitrogen. The spirometer was then opened to the surrounding atmosphere by removing the two corks at its base, thus allowing two apertures each about 2 cm. in diameter. At the beginning of each experiment and at intervals thereafter, samples were drawn off for quantitative analysis of oxygen content. Such experiments were conducted at sea-level pressure with room air and at 300 mm. of mercury total pressure, with a partial pressure of oxygen of 150 mm. Figure 1 gives the partial pressure of oxygen plotted against the diffusion time in min-

utes. The curves show a similar rate of diffusion at the two atmospheric pressures. This suggests that acceleration of the diffusion rate of oxygen does not significantly facilitate respiration at low-nitrogen pressures.

Bert,<sup>9</sup> Boycott and Haldane<sup>10</sup> and Haldane<sup>11</sup> called attention to the theoretical possibility of "bends" if the atmospheric pressure was reduced too rapidly from that of sea level to 300 mm. of mercury or less. Von Schrötter<sup>12</sup> recorded symptoms resembling "bends" after reduction of the total pressure in a tank to 230 mm. in fifteen minutes but believed the symptoms could not have been "bends." In experiments in which the pressure was reduced rapidly to 250 mm. or less, we observed on several occasions one or more of the following symptoms: joint, muscle, precordial and thoracic pains, rapidly spreading skin anesthesia and scotoma. Since then, Armstrong<sup>7</sup> has reported similar experiences. At pressures of 250 mm. of mercury or less, we regularly observed a burning sensation of the eyes and tingling and other paresthesias of the skin. At such pressures, we were also aware of an increase in the effort required for physical and mental work. Inertia prevented a ready response to any task. Armstrong has likened this to the symptoms of anoxia without anoxemia. These symptoms observed independently by Armstrong and ourselves and Armstrong's evidence<sup>7</sup> concerning the formation of nitrogen bubbles and the occurrence of increased intracranial pressure indicate that the possibility of decreased-pressure disease, that is, "bends" and increased vaporization of body water, is a real danger. Although preparatory elimination of nitrogen by breathing oxygen prior to ascent lessens the danger of "bends," this precautionary procedure will not remove the danger that may accompany the increased vaporization of body water at low atmospheric pressures.

Armstrong and Heim<sup>13</sup> have given an excellent description of the adjustment of pressure within and without the middle ear during ascent and descent. In ascent, the expanding air in the tympanic cavity automatically escapes through the eustachian tube. In descent, however, the increasing external pressure closes the eustachian tube, and equilibrium can be established only by opening the tubes by voluntary contraction of their dilator muscles. If the differential pressure becomes greater than 90 mm. of mercury, the muscles can no longer open the closed tubes, and the ready establishment of equilibrium becomes impossible. A differential pressure of 30 mm. causes pain, and an increase in the differential external pressure of 100 mm. or more usually results in rupture of the eardrum. In our experi-

ence, the readiness with which closing of the eustachian tubes accompanied rapid descent varied greatly with the subject, and was also dependent on whether or not congestion and inflammation of the mucous membrane of the nasopharynx were present. Certain subjects encountered great difficulty in preventing closure of the tubes by the usual procedure of swallowing and yawning, even during relatively slow descent, whereas others encountered no difficulty with very rapid descent.

Preliminary observations on the burning of matches and cigarettes revealed a marked increase in their rates of combustion at low-nitrogen, normal-oxygen pressures. With the aid of Professor Philip Drinker, a controlled series of experiments on the rate of burning of carefully calibrated candles was carried out in atmospheres of different nitrogen pressures but with a constant partial pressure of oxygen of 150 mm. of mercury. The results are plotted in Figure 2. This increased rate of combustion at the low-nitrogen pressures introduces a fire hazard that deserves consideration and seems to have been overlooked by other workers. Our data suggest that pressure chambers for low-pressure experiments or pressure-

FIGURE 2.

*This chart shows the increase in rate of combustion or decrease in burning time with a decrease in total atmospheric pressure but a constant partial-oxygen pressure of 150 mm. of mercury. The scales of ordinate and abscissa are logarithmic.*

cabin planes for high-altitude flying should be equipped with adequate fire-extinguishing equipment that will withstand the pressure changes and will not liberate toxic gases.

Finally, the low values for alveolar oxygen observed at total pressures of 250 mm. of mercury or less, in spite of the adequate partial pressures of oxygen, demonstrate a limit to high-altitude flying unless the total atmospheric pressure, as well as the partial pressure of oxygen, is maintained above certain limits. In Table 1, the calculated alveolar oxygen and arterial hemoglobin saturation have been extended to total pressures below, and thus

to altitudes above, the levels at which the alveolar air was actually determined. The risk involved in handling mercury in a closed chamber at markedly reduced pressures, owing to the marked increase in vaporization, was one of the factors that limited our analytical experiments. The data demonstrate that at altitudes above 32,000 feet or at total pressures below 200 mm. of mercury the alveolar oxygen and arterial hemoglobin saturation fall off significantly and with increasing rapidity, in spite of a partial-oxygen pressure of 159 mm. This is accounted for by the normal alveolar carbon dioxide and water-vapor pressures of 40 and 48 mm., respectively. At a total pressure of 140 mm., the sum of these normal alveolar carbon dioxide and water-vapor pressures permits, even if pure oxygen is breathed and the respiratory quotient is 1.0, an alveolar oxygen pressure of but 140 mm. minus 88 mm., or 52 mm., of mercury unless hyperpnea is present. This pressure is not very much above the normal venous oxygen pressure of 40 mm. of mercury. Hyperpnea increases the alveolar oxygen pressure, but unless the atmospheric carbon dioxide pressure is increased, results in decreased alveolar carbon dioxide pressure and alkalosis. An atmosphere of pure oxygen at a total pressure of 130 mm. of mercury or an altitude of 42,000 feet would probably result not only in the same potential dangers due to anoxemia as are encountered in ordinary air at 22,000 feet but also in the dangers due to reduced-pressure disease. Indeed, a recent report by Ceres<sup>14</sup> suggests that effects of the latter are encountered in flights above 30,000 feet.

Thus, to reach altitudes greater than 32,000 feet with any degree of safety, provision must be made for controlling not only the partial pressures of oxygen but also the total atmospheric pressure. This requirement, the middle-ear disturbances in descent, the possibility of "bends" in ascent and of increased vaporization of body fluids at very high altitudes, and the fire hazard at low-nitrogen, normal-oxygen pressures result in great vulnerability at altitudes much beyond 35,000 feet.

#### SUMMARY

Observations related to problems of high-altitude flying made during experiments at atmospheric pressures of 250 to 200 mm. of mercury, corresponding to altitudes between 28,000 and 32,000 feet, are presented and discussed. The increased rate of combustion observed in low-nitrogen, normal-oxygen atmospheres is such as to cause a fire hazard that deserves careful consideration and precautions.

We are indebted to Professor Philip Drinker, Mr. Charles Miller and Miss Elsie MacLachlan for their co-operation and assistance in the course of these experiments.

## CHRONIC GASTRITIS: A GASTROSCOPIC AND CLINICAL STUDY\*

CHARLES W McCLURE, MD,† FREDERICK N SWEETSIR, MD,† AND I R JANKELSON, MD§

BOSTON

THIS communication reports the results of studies of chronic gastritis in adults, the diagnosis of which was made by means of gastroscopy. There were three purposes for making these studies. The first was an investigation of the symptomatology, including an analysis to ascertain whether certain symptoms would permit a presumptive diagnosis of chronic gastritis before performing gastroscopy. The second purpose was to collect statistics on the incidence of chronic gastritis, as observed gastroscopically. A third was an attempt to discover whether the existence of chronic gastritis in the presence of peptic ulcer influenced the symptomatology of the latter condition.

Schindler<sup>1</sup> has developed a practical classification of the main types of chronic gastritis based on gastroscopic studies. An elaboration of this classification, suggested by McClure and Jankelson,<sup>2</sup> embraces the various types of chronic gastritis observed in over 1000 gastroscopic examinations. This classification comprises three main types: the superficial, the atrophic and the hypertrophic, each of which may occur as the simple, ulcerating or hemorrhagic form. Except for the superficial, these terms are self-explanatory. The superficial type is a chronic gastritis in which the mucosa appears inflamed, with redness, swelling and edema and an excess of mucus. The above classification will be followed in describing our observations.

The pathologic characteristics of various types of gastritis were first established by the post mortem studies of Faber<sup>3</sup> His findings were subsequently confirmed by the extensive observations of Konjetzny<sup>4</sup> on gastric mucosa resected during laparotomy, and more recently by Eusterman,<sup>5</sup> Schindler<sup>6</sup> and others However, the practical clinical diagnosis of gastritis was not possible until the development of the Wolf Schindler semiflexible gastroscope in 1932 This instrument permits the direct visualization of mucosal changes such as the various types of chronic gastritis, erosions, superficial ulcerations, purpuric manifestations and other lesions of the gastric mucosa not otherwise readily demonstrable during life As a result of the use of this gastroscope, a large literature on

gastroscopic findings has accumulated and has been correlated by Schindler,<sup>1</sup> Swalm, Jackson and Morrison,<sup>7</sup> Swalm and Morrison,<sup>8</sup> Schindler and Murphy<sup>9</sup> and in reviews by Cheney,<sup>10</sup> by Jones et al,<sup>11</sup> and by others. All the observers agree that chronic gastritis is a common gastroscopic finding. This frequency is well illustrated by Schindler's<sup>12</sup> tabulation of the gastroscopic findings in 1000 patients, in whom the lesion was present in 42 per cent, Carey<sup>13</sup> found it in 44 per cent of 700 gastroscopies. Nevertheless, more recently Ruffin, Brown and Clark<sup>14</sup> conclude from the results of their gastroscopic observations that the reported frequency of chronic nonspecific gastritis is to be seriously doubted.

Most of the reported gastroscopic studies have been largely concerned with descriptions of the gross anatomic changes observed, and but incidentally with the accompanying symptomatology. How little differential diagnostic knowledge has been accumulated is illustrated by a quotation from Swalm et al.,<sup>7</sup> "The symptoms of gastritis are so variable that they range from a complete absence of symptoms to flatulent dyspepsia to perfect mimicking of peptic ulcer with its hunger pains and food or alkali relief with hematemesis." Nevertheless, more recent studies<sup>9 15-17</sup> suggest the possibility of clarifying the symptomatology. These studies indicated that in patients with gastritis the appetite was often poor, although it might remain unaffected but was not found to be increased. Relief after food was found to be less common than in ulcer, indeed, food not infrequently aggravated the symptoms. Epigastric distress or true pain was the rule and was often of the delayed type. Severe epigastric pain, not referred, was reported only in the hypertrophic form.<sup>15</sup> Hemorrhage was an important complication.<sup>1 15-20</sup> It was suggested<sup>9</sup> that the atrophic type may be differentiated by the general symptoms of marked weakness, sense of fatigue, emotional depression, sore tongue and paresthesias. Although the degree of gastric acidity was reported<sup>9 15 21</sup> to be variable, achlorhydria or hypoacidity was more commonly found in the atrophic type and normal or increased values in the superficial and hypertrophic forms.

The incidence of any pathologic condition is always of great importance. For this reason, we determined the frequency of chronic gastritis by means of gastroscopic observations in 611 consecutive patients; it was present in 269, an incidence of

44 per cent. Although 99 (37 per cent) of these patients showed mixtures of the different types of gastritis, in each of them one type predominated sufficiently to permit a classification as essentially hypertrophic, atrophic or superficial. On this basis, 150 (56 per cent) were of the hypertrophic, 51 (19 per cent) of the atrophic, and 68 (25 per cent) of the superficial type, an incidence of 25 per cent, 8 per cent and 11 per cent, respectively. The findings are comparable with those reported by other observers,<sup>11,14</sup> and show that various types of chronic nonspecific gastritis are of common occurrence. The associations of the types of gastritis mentioned above were hypertrophic with superficial in 33 cases, hypertrophic with atrophic in 29 cases, atrophic with superficial in 25 cases, hypertrophic with superficial and atrophic in 4 cases, and ulcerating or hemorrhagic ulcerating with either hypertrophic or atrophic in 8 cases. These figures represent incidences of 5.4, 4.7, 4.1, 0.7 and 1.4 per cent, respectively.

For the purpose of evaluating the symptomatology of chronic gastritis, 75 patients were subjected to comprehensive studies. Obviously, the thoroughness of such studies is an essential factor governing their value. For this reason, with certain exceptions, all observations and procedures incident to the clinical study were carried out with the utmost care by at least one of us; and in every case gastroscopic examination was made by two of us. The exceptions mentioned refer to the radiographic and laboratory procedures, the majority of which were performed in the appropriate departments of the hospital.

The clinical studies showed that a small number of patients were troubled with constipation, but in most of them the bowel habits were not unusual. Weight loss was sustained by 6 patients with hypertrophic and by 4 with atrophic gastritis. The loss was approximately at the rate of 1 pound a week and was never extreme. Twenty-nine of the patients with hypertrophic and 25 with atrophic gastritis showed no weight loss. Thus, changes in weight in this series of patients were not of clinical importance. Except as the result of gross hemorrhage, the blood and stools showed nothing demonstrably abnormal. The Hinton test on the blood serum was negative in all the patients, as was the usual clinical examination of the urine.

Thirty-nine of the patients presented hypertrophic gastritis, and 29 atrophic gastritis. Of the former, 34 were men and 5 women, whereas of the atrophic, 17 were women and 12 men. Thus, men predominated greatly in the hypertrophic and women to a lesser extent in the atrophic type.

Table 1 shows that the ages varied from twenty to eighty years, with a rather even distribution of the hypertrophic cases for each decade; the atrophic type showed lessened incidence in the sixth and eighth decades. However, in general the

70 to 80.....	7	1

age incidences found for the two types of gastritis are comparable.

The duration of the symptoms for both types of gastritis is outlined in Table 2. In general, the duration was comparable in each group. This tabulation also indicates that gastritis is a chronic condition.

Of the 68 patients showing hypertrophic or atrophic gastritis on gastroscopy, 20 had a duodenal ulcer and 1 a gastric ulcer, as diagnosed by

TABLE 2. *Duration of Symptoms.*

x-ray studies, and 6 presented x-ray evidence of gall-bladder disease or had undergone cholecystectomy. The presence of the gastric ulcer was verified by gastroscopic observation. The remaining 41 cases were uncomplicated; an analysis of the symptomatology of these patients is given in Table 3. Of the 41 patients with uncomplicated chronic gastritis, 30 complained of epigastric discomfort or mild pain, and 9 of severe epigastric pains. Thus, epigastric discomfort and pain were the commonest symptoms. As the table shows, they were variably related to the time of taking food, and they were also variably relieved by the ingestion of food or alkali. The peptic-ulcer characteristic of periodicity of symptoms was described by 24 of the patients. Good appetite was present in 32, and anorexia in 12. Vomiting was a prominent symptom in 15, and hematemesis in 5. Of the 2 patients with atrophic gastritis without pain

or discomfort, one complained of nausea and fatigue and the other complained of fatigue and also of the regurgitation of small amounts of bloody liquid. Fatigability occurred in 33 per cent of the atrophic, but was absent in the hypertrophic group.

The data correlated in the table are the results of careful scrutiny of each patient's history. They indicate the basis for concluding that, except for fatigability and absence of epigastric complaint in 2 patients of the atrophic group, the symptomatology of hypertrophic and atrophic gastritis is similar. The case scrutiny also disclosed that 10

"Nervousness"	7	9
Fatigability	0	9

patients in these two groups showed symptoms characteristic of peptic ulcer. An analysis of the symptomatology of the remaining 31 cases shows certain symptoms differing from those of the typical peptic-ulcer syndrome: no time relation of pain or discomfort to meals, 25 cases; pain or discomfort augmented by food, 9 cases; pain or discomfort not relieved by food or alkali or by both, 5 cases; constant or intermittent pain or discomfort, 17 cases; constant pain or discomfort not relieved by food and associated with sharp, knifelike epigastric pain definitely related to meals, with relief by alkali, 6 cases; anorexia, 12 cases.

Of the 21 patients showing both chronic gastritis and ulcer, modification of the usual ulcer syndrome occurred in 4. In 3, duodenal ulcer was present; of them complained of anorexia, the second had anorexia, with no relief by food, and the third, in addition to these symptoms, stated that there was no time relation between the onset of pain and food intake. The fourth patient, who had a gastric ulcer, experienced no relief from pain after either food or alkali.

The presence of chronic gastritis caused no demonstrable influence on the symptoms presented by the 6 patients with chronic cholecystitis or by those who had undergone cholecystectomy.

In this study, x-ray observations were found to be of inconsequential value as a direct aid in the diagnosis of gastritis. However, barium gastrointestinal x-ray studies were of essential value in determining the presence or absence of esophageal lesions, cancer, ulcer of the stomach, pyloric obstruction, duodenal ulcer and lesions elsewhere in the small or large bowel. Radiography was of similar value in relation to the diagnosis of diseases of the gall bladder.

## DISCUSSION

Chronic gastritis is known to be a common pathologic entity; it was observed gastroscopically in 44 per cent of our patients and in comparably high percentages by others.<sup>12, 16</sup> These high incidences resulted from limiting observations to those patients presenting gastric complaints. For this reason, the findings do not denote the frequency in the general population. The latter may be calculated by the use of the mean average of figures reported by the Commission on Medical Education,<sup>22</sup> which shows that 13.4 per cent of all patients visiting outpatient departments present digestive complaints. If gastroscopy reveals chronic gastritis in 44 per cent of these cases, the incidence among the general population is approximately 6 per cent.

The types of gastritis can be divided into primary and secondary groups.<sup>2</sup> The latter group includes chronic gastritis occurring in the course of either an established causal or a possibly causal pathologic condition. In our cases that were carefully studied clinically, 34 (45 per cent) accompanied peptic ulcer or gall-bladder disease. This finding confirms the conclusion drawn from a much larger number of less carefully controlled observations that the condition is a secondary entity in 50 per cent of the patients in whom it is observed. On the basis of this percentage, proper calculation shows that the incidence of primary chronic gastritis among the general population is about 3 per cent. In the aggregate, this percentage represents a large number of patients. Furthermore, the results of the present investigation and those of other observers<sup>16-17, 23</sup> show that it is a chronic disturbance, causing mild to serious and even incapacitating disability. It is also established that the condition is not infrequently mistaken for peptic ulcer, whereas it may be confused with carcinoma of the stomach,<sup>6, 24</sup> which has caused useless laparotomies.<sup>24</sup> Thus, chronic gastritis affects a sufficiently large number of patients to make its clinical investigation very important.

Morphologically, primary gastritis is indistinguishable from the secondary type, and clinical

studies furnish the only means of differentiation. Obviously, without this differentiation, the symptomatology may include a variety of manifestations due to a causative primary disease. For this reason, the analysis in this communication represents the findings only in those patients who have been intimately studied and observed for a prolonged period. This explains why the findings are reported in only 75 of nearly 400 patients in whom a gastroscopic diagnosis of chronic gastritis was made; superficial gastritis has not been discussed because the number of cases studied intensively was too limited.

A correlation of symptoms occurring in primary chronic gastritis that differ from those of the typical peptic-ulcer syndrome has already been given. These symptoms are merely suggestive, not diagnostic, of the presence of chronic gastritis. Furthermore, gastric analyses showed nothing of positive diagnostic significance regarding either the presence of gastritis or the differentiation of the two types. In addition, x-ray studies were often of inconsequential value in diagnosing the presence of gastritis. Thus, the only dependable method of diagnosing chronic gastritis or differentiating its various types is afforded by gastroscopy.

The symptomatology of chronic primary gastritis usually resembles that of peptic ulcer. However, it is occasionally suggestive of cholecystitis, and more rarely of carcinoma. In the differential diagnosis, one should consider not only these entities but also all others that may cause upper abdominal digestive symptoms, and when hematemesis has occurred, all its causes should be kept in mind. Having thus established gastroscopically the presence of gastritis, one can decide whether it is primary or secondary only by clinical means. Also, what role the gastritis plays in the production of the symptomatology can be decided only by proper clinical interpretation.

A factor useful in differential diagnosis is furnished by the findings in the 10 patients whose symptoms were typical of peptic ulcer. The differential feature is the failure to find x-ray evidence of peptic ulcer, gall-bladder disease or any other cause for the symptomatology. This is a diagnostic feature stressed by Rivers and Smith.<sup>17</sup> Fatigability apparently affords another diagnostic feature since, as emphasized by Schindler and his associates,<sup>15</sup> it is a symptom of atrophic gastritis, and since it was not observed in any case of the hypertrophic type.

Hematemesis resulting from gastritis and occurring in the absence of peptic ulcer, carcinoma, polyp, varicose veins or blood dyscrasias was observed in 3 cases of hypertrophic and 2 of atrophic

gastritis; it was caused by an ulcerating type of gastritis—that is, many superficial ulcerations and fissures were scattered throughout the mucosa. The bleeding varied from mild to severe, but was not fatal.

To study the effect of chronic gastritis on the symptomatology of peptic ulcer, 21 cases of the latter disease were investigated. In only 4 of these were the symptoms apparently modified by the presence of the gastritis, the modification consisting of anorexia or absence of relief of pain by food. Thus, these symptoms, when peptic ulcer is known to exist, suggest the presence of gastritis. On the other hand, their absence does not exclude gastritis.

The tabulations already presented show that the age incidence and chronicity of the hypertrophic and atrophic types of gastritis are comparable. The findings in relation to age incidence confirm those in 21 cases of hypertrophic and 59 cases of atrophic gastritis collected from the literature.<sup>7, 9, 23, 25, 26</sup>

### SUMMARY

The symptomatology of gastroscopically demonstrated primary chronic gastritis was studied and analyzed. Certain symptoms were found to suggest the presence of chronic gastritis.

Hematemesis was an important complication of primary chronic gastritis.

Fatigability was a symptom characterizing primary atrophic gastritis.

The age incidence and the chronicity of hypertrophic and atrophic gastritis were comparable.

The presence of chronic gastritis can apparently be demonstrated only by means of gastroscopy. Nevertheless, the diagnostic significance of the gastroscopic findings must be governed by clinical interpretation.

The incidence of chronic gastritis among our patients was 44 per cent, and there was an approximately even division of the secondary and primary forms. It is estimated that the incidence of primary chronic gastritis among the general population is about 3 per cent.

The symptomatology of peptic ulcer was occasionally slightly modified by the presence of a demonstrable gastritis.

## MEDICAL PROGRESS

### RECENT DEVELOPMENTS IN AVIATION MEDICINE\*

JOHN F FULTON, M.D.†

NEW HAVEN, CONNECTICUT

UNDER the stimulus of the present emergency, many laboratories in this country and abroad are investigating physiologic problems encountered in high-altitude combat flying. Despite military restrictions imposed by war, the literature of aviation medicine has grown continuously, and the National Research Council has recently authorized the compilation and publication of a classified bibliography of aviation medicine, which will presently be published as a supplementary number of the *Journal of Aviation Medicine*. The following review summarizes material issued within the past two years.

The performance of modern military aircraft taxes the physiologic limitations of the pilot in many ways, and although vast sums have been spent by the Government in the design of aircraft, little so far has been appropriated for study of the

physiologic limitations and protection of the pilot; this lack continues, despite the fact that in Germany some twenty independent laboratories of aviation medicine are supported by the government. The war in the air has come to be in a very real sense a physiologic war, since the limitations of air combat at the present time lie more with the pilot than with the plane, and the government that succeeds in adequately protecting the pilot through study of his physiologic needs will gain strategic advantage that will undoubtedly be decisive in determining the outcome of the conflict. It is therefore incumbent on all who are actively concerned in the present war to become familiar with the general principles of aviation medicine, especially as they relate to high-altitude combat flying.

The more important advances of the last two years relate to the following: the physiologic effects of acceleration; the use of oxygen at high altitudes; air embolism and its prevention; and anoxia of the adrenal glands. The topics are considered in this order; problems of pilot selection and training are not touched on.

#### PHYSIOLOGIC EFFECTS OF ACCELERATION

It is well known that modern combat flying, especially the dive bombing maneuver, causes the development along the longitudinal axis of the body of centrifugal forces that tend to draw blood

\*All articles in this series will be published in book form the current volume in *Medical Progress Annual*, 1940 (Springfield Illinois: Charles C Thomas Company, 1941) \$4.00.

†From the Laboratory of Physiology Yale University School of Medicine Sterling Professor of Physiology Yale University School of Medicine.

In England the Flying Personnel Research Committee has directed research for the Royal Air Force in Canada a similar committee has been set up since the beginning of the war and in the United States the National Research Council at the request of the armed services formed the Committee on Aviation Medicine in October, 1940. These three committees along with the air corps which they serve are responsible for the principal direction of research endeavor in aviation physiology in the allied countries. These committees have thought fit to publish some of their newer disclosures but other data having strategic military significance cannot be made public at the present time, and hence a review of the subject is to this extent restricted by the exigencies of war. General principles can be discussed but specific details of equipment must necessarily be left for the future.

away from the head, and so to induce a state of collapse from acute anoxia of the brain. The ultimate effect of a given acceleration depends on four factors: the magnitude, the duration, the direction of acceleration, and the physiologic condition of the pilot at the time the acceleration develops. An excellent discussion of the underlying physical principles is found in a recently published volume by Grow and Armstrong,<sup>1</sup> and in a work by Phillips and Sheard.<sup>2</sup> The recent German literature, with a surprising amount of experimental detail, is given by Ruff and Strughold.<sup>3</sup> Data from English sources are summarized by Livingston<sup>4</sup> and Whittingham.<sup>5</sup> All authorities agree that a healthy young adult can withstand a positive acceleration acting along the vertical axis of the body of 4.5 g (four and a half times the force of gravity) for approximately five seconds. Thereafter, vision becomes dim (the so-called "blackout"), and consciousness may be entirely lost. But from the point of view of safety in aviation, the state of the pilot's co-ordination during the seconds prior to loss of consciousness is vital, for judgment and co-ordination are poor when relative cerebral anoxia exists, irrespective of its cause. When one is flying at a high altitude under conditions of relative anoxia to start with, a small degree of acceleration may cause blackout much earlier than at sea level.

The direction of acceleration is also important, and recent studies indicate that the body withstands accelerations applied along the horizontal axis of the body far more successfully than along the vertical axis. Negative accelerations toward the head are highly dangerous because of exaggeration of the carotid-sinus reflexes. Indeed, the average young adult can seldom withstand more than 3 g of negative acceleration for five seconds without "seeing red" and having retinal hemorrhages. This accounts for the fact that stunt fliers are loath to indulge in any form of acceleration when flying upside down.

The condition of the organism has much to do with the capacity to withstand acceleration. All test pilots insist that an alcoholic spree of an evening considerably diminishes tolerance for positive acceleration the next day. More significant than this, however, is the fact, recently emphasized in the German literature,<sup>3</sup> that tolerance is seriously lowered by an empty stomach, and all German fliers are urged before going on dive-bombing maneuvers to have a full meal. The effect of food is explained by the Germans as being probably due to the filling of the visceral blood vessels—because they are filled, further

blood is not readily forced into them by centrifugal action. Blood chemistry is not discussed.

In the recent German literature, the following factors, in addition to the full stomach, are mentioned as favoring the pilot's capacity to withstand acceleration:

*Carbon dioxide.* The inhalation of 5 or 6 percent carbon dioxide, through augmenting the cerebral circulation, increases resistance to acceleration by 1 to 2 g.

*Vasoconstrictor drugs.* Any pharmacologic agent that increases the tone of the capillary wall improves one's ability to withstand acceleration. Pituitrin, adrenalin and adrenocortical hormone have all been mentioned in this connection, but precise data concerning them are not available.

*Pneumatic belts.* Mechanical constriction of the abdomen and of the lower extremities has also been proposed in both the German and English literature to minimize the rush of blood from the head to the visceral bed and the lower extremities. Of these mechanical devices, pneumatic belts and pneumatic trousers have been the devices usually discussed. The Germans state that a pneumatic belt may increase tolerance by 1.0 to 1.5 g, but no one of the present belligerent countries has permitted publication of detailed reports concerning these devices.

*Water suits.* The Germans have also reported on a water suit designed for the prevention of blackout, and although they claim that it notably improves resistance to positive acceleration they state that it is unsatisfactory for other reasons.\*

*Posture.* In a recent paper by Ruff,<sup>6</sup> the problem of posture in relation to acceleration was discussed. The Germans, it appears, favor crouching posture, with flexion of the legs against the abdomen, as one particularly suitable for protection of the pilot against acceleration. If the pilot lies supine or prone at the end of a dive-bombing maneuver, he is also less subject to negative accelerations, but in these postures he is unable to see out or to maneuver his plane without special redesigning of the cockpit and the cockpit controls.

The problem has been studied in this country by Armstrong and Heim,<sup>7</sup> and the physiologic

\*To quote Grow and Armstrong<sup>1</sup>: "The water suit is a closely fitting water-proof garment which is worn next to the skin. What little space is left in the suit after it is put on is filled with water or other suitable fluid. This causes the flier to 'float' in the suit, and during acceleration the water presses on the body equally in all directions. As a consequence the normal effects of acceleration are replaced by a uniform compression of the body which, it is estimated, could be tolerated without difficulty up to 15 g or more."

changes accompanying positive acceleration are admirably summarized by Poppen<sup>8</sup> as follows

Our findings confirm those of Armstrong and Heim. It is scientifically interesting that by these two methods of approach the findings were practically identical. Dr. Drinker and I found the following chain of physiological events incident to high positive accelerations: (i) A drop in carotid pressure is a result of the hydrostatic, centrifugal action on the arterial column. (ii) A drop in jugular pressure incident to the same action upon the venous column. (iii) The centrifugal effect upon the venous column is sufficient to reduce the volume of blood reaching the right auricle. This results in a reduced per beat and per minute output of the heart. This causes a secondary drop in carotid pressure superimposed upon direct arterial effect. (iv) The combined effects reduce the carotid systolic pressure, under moderate accelerations, from an average of 130 mm. of mercury to between 60 and 70 mm. (In one case under 6 g, the pressure dropped to 16 mm.) (v) The reduced pressure causes a profound slowing of the circulation through the brain. (vi) A transient local cerebral anoxemia results. This is adequate to explain the symptoms of high acceleration.

We found further that the drop in carotid pressure was proportional to the acceleration. It increases on successive accelerations at frequent intervals. If the acceleration is discontinued before the secondary reduced heart output, the drop in carotid pressure is insufficient to cause severe anoxemia. This explains the statement often made by test pilots that they would prefer 10 g for 15 seconds to 5 g for 3 seconds.

It should be noted that all factors tending to improve the body's resistance to positive acceleration are those that tend to keep blood in the head. Hence it may be concluded that the phenomenon of blackout and loss of consciousness, which may occur within five seconds of the beginning of the acceleration, is probably due solely to acute anoxia and cannot be attributed to any direct effect of acceleration per se on the cortical neurons.

#### USE OF OXYGEN AT HIGH ALTITUDES

It has long been recognized that oxygen is essential for operations at high altitudes, but the reluctance of the older pilots to use it and the conservatism of the commercial air lines in supplying oxygen to passengers have tended to distract attention from the need for oxygen in the lower altitude ranges. Recently, however, there has been a change of emphasis concerning the use of oxygen, there have likewise been improvements in modes of administration of oxygen and also in supply. A general discussion of the effects of anoxia on the heart and other organs has recently been given by Hoff<sup>9</sup> and also by Gemmill.<sup>10</sup>

*Need for oxygen at the lower altitude ranges.* The studies of McFarland,<sup>11</sup> Barach,<sup>12</sup> and many observers in Europe have indicated that mental functions are gravely impaired when human beings are exposed to an oxygen partial pressure equivalent to that encountered at an altitude of 12,000 feet. Thus, when a series of Barach's stu-

dents breathed 13 per cent oxygen over a period of three hours, conspicuous emotional changes developed that were characterized at first by overconfidence, elation and ideational fixations and after an hour or so passed over into a feeling of dullness, lethargy, headache and lack of emotional restraint. Experienced pilots flying without oxygen at 12,000 feet have frequently given testimony of similar strain, irritability, discomfort and bad judgment.

If such grave changes are manifest at 12,000 feet, one naturally wishes to know what other functions may be impaired at the same time, and how soon in the course of ascent the changes can be recognized. Little by little, evidence is accumulating that vision, especially night vision,<sup>14, 15</sup> becomes conspicuously impaired. The gunner begins to lose accuracy of aim even at 8000 feet, the reaction time of the pilot in response to radio signals, or in facing danger in combat, is increased between 5000 and 10,000 feet, varying markedly with individual fliers.

In the cardiac sphere, White<sup>16</sup> reports on electrocardiograms taken on 45 supposedly normal persons exposed to altitudes as high as 20,000 feet with varying rates of ascent (see also Hoff<sup>9</sup>). The changes in the electrocardiogram, especially in the T wave, were noted in all subjects at about 5000 feet, the changes being conspicuous if the rates of ascent were rapid. U waves also became prominent with increasing anoxia, and since all changes disappeared on administration of oxygen, White concludes that myocardial anoxia is the cause of the alterations. As a result of his studies, White recommends that, to secure physiologic normality in a pilot, oxygen should be taken at altitudes above 5000 feet and that it should be mandatory in any flight exceeding 7500 feet. Similar changes in the electrocardiogram of animals have recently been observed by Wiggers<sup>17</sup> and in unpublished studies in this laboratory.

The use of oxygen in the lower altitude ranges has also become an established practice among high altitude squadrons for the sake of washing out nitrogen, which in the higher altitude ranges is likely to give rise to 'bends'. Benson<sup>18</sup> finds that in normal subjects there is no change in the electrocardiogram if pure oxygen is breathed up to 30,000 feet.

*Oxygen mask.* Oxygen masks have been the subject of much discussion and study since the outbreak of the war. The BLB mask was the only one commercially available in the United States at the beginning of the present war, and the old pipestem method of administering oxygen was still in use. The pipestem has proved dangerous and difficult for high altitude operations, because it prevents the pilot from speaking and

is likely to drop from his mouth in the event of a serious emergency. All opinion, therefore, is in essential agreement that a face mask must be used for oxygen administration.

The original B.L.B. mask, both the nasal and the auronasal, had, for pilots, disadvantages that do not apply to patients lying prone in bed, for whom the masks were originally devised. One of the most serious difficulties was that at higher altitudes the valves of the mask tended to freeze, and the mask itself tended also to freeze to the face and thus irritate the skin.

Many special masks have lately been proposed with a view to obviating these difficulties. Thus, Barach and Eckman<sup>19</sup> describe an improved nasal mask. Other masks are now undergoing service tests in this country and abroad, and it is hoped that one will be found answering the ideal specifications recently set forth by Poppen,<sup>20</sup> namely, that the mask must be comfortable to wear, that it must have provision for microphone communication, that its valves must not freeze at  $-50^{\circ}\text{C}.$ , and that some provision must be made to vary the supply of oxygen in accordance with the respiratory needs of the pilot as these change. The actual details of how these requirements are being met cannot be discussed here.

**Oxygen supply.** Oxygen tanks remain the chief source of supply in all combat ships. In large bombers having a personnel of eight or ten during flight, in which missions are long and the altitude high, the oxygen tanks add very considerably to the weight load, and hence various proposals have been made to manufacture oxygen in flight. It is not a military secret that no one of the proposals for separating oxygen in the air has so far proved satisfactory. The new aluminum alloy tanks, however, have very considerably diminished the weight load, but since they are more vulnerable to machine-gun penetration they probably form a greater hazard to the pilot and the ship than the older, heavier oxygen tanks.

Pressure-cabin planes have so far not proved feasible for light combat craft.

#### AIR EMBOLISM AND ITS PREVENTION

During the course of the present war, certain pilots in high-altitude squadrons have experienced grave symptoms that could not be attributed to anoxia, acceleration or any form of metabolic disturbance. Susceptible persons, some at altitudes as low as 25,000 feet, developed paresthesias, with numbness and itching, sometimes restricted to the face, but often occurring sporadically all over the body. Later, aches and a sense of deep localized pressure often developed in one or more of the peripheral joints, especially the knuckles and wrists and occasionally also in other joints, particularly

if there had been previous injury. These premonitory symptoms are followed sometimes quite quickly by the development of intolerable deep pain variously described as rheumatic or like that of a toothache, and often referred to a given joint or to a previously injured long bone—one of the best recent descriptions of this type of pain is that of Streltsov,<sup>21</sup> of the Pavlov Laboratories in Moscow. These intense deep pains are indistinguishable from those experienced by divers in the familiar syndrome of the "bends."<sup>22</sup> Recently, diving crews familiar with the bends have been subjected to decompression, and they have experienced at altitudes equivalent to 28,000 and 35,000 feet symptoms closely parallel with those which they had had when emerging too rapidly from an undersea dive.<sup>23</sup> Severe bends may be followed by collapse, pallor, sweating and respiratory difficulty all developing with catastrophic rapidity. Such collapse has been thought to be due to sudden pulmonary air embolism.

Proof that high-altitude bends are caused by the liberation of nitrogen has been somewhat difficult to establish by direct observation, but the indirect evidence of similarity of symptoms is highly impressive (see Armstrong<sup>24</sup>). Quite recently, Walsh and Boothby<sup>25</sup> have found that bubbles begin to appear in the cerebrospinal fluid of human beings in a decompression chamber when subjected to a pressure equivalent to an altitude of 12,000 feet. The bubbles were fine, like those rising in good champagne. They became larger and more numerous at pressures approximating those of 28,000 feet, but after ten minutes' exposure to such altitudes the bubbles decreased in number and size, and later disappeared. The cerebrospinal-fluid pressure in these circumstances rose to a level 3 cm. higher than normal. This was believed to be due to the expansion of air bubbles.<sup>26</sup>

If bends occur as commonly as one might be led to suppose from the early reports, especially from observations made on men of older age groups, this condition is clearly a serious hazard for fliers. However, it has been found by Armstrong<sup>24</sup> and by many others who have lately investigated the problem that there is a large individual variation in susceptibility and that bends occur less commonly in the younger age group, for example, from eighteen to twenty-four, the average age of the combat flier, than in the older age group. Decompression-chamber tests suggest, moreover, that at least 50 per cent of a population of young male adults can withstand altitudes as high as 40,000 feet for periods of from one to six hours without developing bends. Hence it has been suggested that the high-altitude squad-

rons be selected on the basis of decompression-chamber tests

Since bends are undoubtedly due to the formation of nitrogen bubbles in the tissues, an obvious suggestion would be to rid the tissues of their nitrogen by replacing the latter with helium<sup>21</sup> or by preoxygenation. This proposal has been studied by Behnke<sup>8</sup> and others. Armstrong and Heim,<sup>9</sup> for example, find that inhalation of pure oxygen from half to one hour before ascent prevents bends. But Whittingham,<sup>40</sup> in reviewing Armstrong and Heim's paper, mentions that observations in England have shown that inhalation of oxygen merely delays the onset of bends and does not actually prevent it. Furthermore, the recently published curves of Behnke and Willmon<sup>22</sup> indicate that at least five hours are required to eliminate nitrogen from the body by oxygen inhalation, and that owing to the fatty deposits in the marrow of the long bones, the bone marrow tends to hold its nitrogen more firmly than other tissues do. Since some at least of the deep pain associated with bends probably arises from bubble formation in the long bones, it would be essential to have at least five hours of preoxygenation to give a subject complete immunity from the distressing syndrome.

It is obvious, therefore, that from the point of view of combat flying it is not feasible to protect a flier by causing him to breathe oxygen for five hours before going up. But with careful selection of personnel for high altitude operation, and with the delaying effects of pure oxygen from the ground up, bends cease to be a serious problem in military aviation.

Likewise for practical reasons, the use of helium to replace nitrogen has not been found feasible for combat pilots.

#### ANOXIA OF THE ADRENAL GLANDS<sup>31</sup>

In a little quoted paper by Kellaway,<sup>32</sup> published in 1919, it was pointed out that a cat subjected for several hours to low-oxygen tension exhibits a rise of blood sugar and an increase of heart rate, both of which the author attributed to active secretion of the adrenal medulla during decompression, paradoxical dilatation of the denervated pupil occurred, a phenomenon that had already been proved to be due to the liberation of adrenaline, since section of the splanchnic nerves completely abolished the dilatation. When the splanchnic nerves were sectioned, the blood-sugar elevation was abolished initially, but Kellaway encountered several animals, not fully accounted for in his protocols, in which after more prolonged exposure, the blood sugar actually rose.

Kellaway was not aware of the significance

of the adrenal cortex, and it remained for Evans,<sup>33</sup> fifteen years later, to elucidate its action.\* The latter observed a striking increase in the glycogen content of the liver and in the glucose level of the blood of rats exposed to half an atmosphere pressure in a decompression chamber, and he proved that the phenomenon failed to occur after adrenalectomy. He did not cut the splanchnic nerves, but he found that adrenocortical hormone restored the blood sugar and glycogen response in a specific manner. When exposed for twenty-four hours to the rarefied atmosphere, containing 10.5 per cent oxygen, the glycogen content of the liver of a normal animal increased ten to twenty times above its resting level, and the blood glucose increased markedly. Since the total carbohydrates in the animal had become augmented, it was evident that glucose must be formed from noncarbohydrate sources, probably entirely from proteins.

These observations have more recently been confirmed by a number of investigators, notably by Long et al.<sup>34</sup> and by Thorn and his collaborators.<sup>37</sup> Armstrong and Heim<sup>28</sup> found that hypertrophy of the adrenal glands occurs when animals are exposed repeatedly to low partial pressures of oxygen, suggesting that some substance is elaborated in the adrenal cortex when an animal is adjusting to anoxia. Strong confirmatory evidence pointing in this direction came in 1937 from Giragossintz and Sundstroem,<sup>39</sup> who pointed out that it took ten times as much adrenocortical extract to maintain adrenalectomized rats at half an atmosphere as it did at sea level. Very little clinical evidence is as yet available concerning the behavior of the adrenal cortex in man exposed to high altitudes, and it is not yet clear whether the administration of adrenocortical hormone in man facilitates his adjustment to high altitude or improves his performance. The results recently reported by Kendall<sup>40</sup> suggest that the corticosterone fraction rather than the desoxycorticosterone is responsible for the carbohydrate changes and possibly, therefore, for the adjustment to altitude. Armstrong<sup>23</sup> has suggested that the physical collapse which occurs in combat pilots after excessive exposure to diminished oxygen pressure may be due to atrophy of the overworked adrenal glands, the syndrome being essentially similar to that of Addison's disease. Huddleson and McFarland<sup>41</sup> have found that the administration of adrenocortical hormone is beneficial in cases of psychasthenia.

\*Observations bearing on the reaction of the adrenal glands in anoxia, but in which no clear distinction is made between the adrenal cortex and the adrenal medulla, are found in the papers of Binet and Labrosse<sup>42</sup> and Housay and Rietti.<sup>43</sup>

## CASE 27331

## PRESENTATION OF CASE

*First Admission.* A thirty-eight-year-old, Irish-born, single domestic was admitted to the hospital complaining of joint pains.

Two and a half years before admission, the patient began to suffer from attacks of arthritis characterized by redness, heat, swelling and limitation of motion in the various joints. Her feet, shoulders and sternoclavicular joints were first involved, and later her knees and the small joints of the fingers and hands. These attacks lasted for long periods, and to control the pain she took Oxyliodide, a proprietary drug containing cinchophen.

One year before admission, the patient became progressively more tired and noticed an increasing jaundice of the skin, without pruritus. Vomiting ensued, the stools became pale, and drowsiness was so pronounced that she slept most of the time. Abdominal distention developed, and a paracentesis was performed on three occasions. Severe nosebleeds occurred, and at the time of admission the patient had lost 20 pounds. She was in another hospital the best part of three months, and during this time the joint pains were in abeyance. Her strength and appetite gradually returned, and the jaundice faded; five months before entry, however, the joint pains returned.

The family history was irrelevant. Seven years before admission, the patient had had "jaundice," for which she was treated in another hospital. Nosebleeds had occurred for several months before the onset of her illness two and a half years previously.

Examination showed a poorly nourished, slightly jaundiced woman with minimal generalized adenopathy. There were signs of fluid at the right base. The heart was not enlarged, but a systolic murmur was audible; the blood pressure was 150 systolic, 80 diastolic. The abdomen was protuberant, with shifting dullness, and a small umbilical hernia was noted. The liver was palpable two fingerbreadths below the costal border, and the spleen was easily felt. The fingers were tapering and spindled; the ankles, elbows and knee joints were swollen, tender and limited in motion.

The temperature, pulse and respirations were normal.

The urine was normal. The stools were guaiac positive on one occasion but negative on six other examinations. Examination of the blood showed a red-cell count of 3,360,000 with 60 per cent hemoglobin, and a white-cell count ranging from 3400 to 6400, with a normal differential. The blood film showed moderate hypochromia, anisocytosis and poikilocytosis. The blood Hinton reaction was negative. The blood nonprotein nitrogen and uric acid were normal. The serum protein was 4.7 gm. per 100 cc. The serum van den Bergh was normal indirect, and the icteric index 4. The Takata-Ara test was strongly positive, and the bromsulphalein excretion showed 10 per cent retention of the dye. The blood sedimentation rate was 0.43 mm. per minute. Gastric analysis showed no free fasting acid but did show 10 units after histamine; a guaiac test was positive. A sugar-tolerance test was normal, the fasting value being 85 mg. per 100 cc. The basal metabolic rate was +19 per cent. An electrocardiogram showed slight left-axis deviation.

X-ray films of the involved joints showed narrowing of the joint space, irregularity of the articular surface, new-bone formation about the margins and marked decalcification. The Graham test showed the presence of a small stone within a poorly functioning gall bladder. Examination of the colon, sinuses and jaws was negative save for a single incisor-root abscess. A film of the chest showed a high right diaphragm, a slightly dull right cardiophrenic angle and a slight shift of the heart to the right.

During a three months' stay in the hospital, the patient's oral temperature frequently reached 100°F. On one occasion, she was given 3 gr. of Nembutal and ¼ gr. of morphine, with the result that she slept for three days and her temperature rose to 102°F. The patient was maintained on a regimen of high vitamins and physiotherapy, but responded so poorly that she was discharged to a hospital for chronic patients. On one occasion, an abdominal paracentesis yielded 6500 cc. of light-yellow fluid.

*Final Admission* (five years later). During the intervening five years, the joint symptoms and disability did not progress, but the patient had slight recurrent ascites and jaundice from time to time. She was readmitted complaining of nonradiating subxiphoid postprandial pain, usually followed by nonprojectile vomiting and unrelieved by food or milk. For two weeks, she had been unable to keep anything down, even water. The vomitus was never blood stained, and there was no change in bowel habits, or blood by rectum.

Examination was unchanged, except that the liver edge was no longer palpable (one observer excepted) and that there were no signs of ascites. The blood pressure was 130 systolic, 80 diastolic.

The temperature, pulse and respirations were normal. The urine was normal except for +++ test for bile on one occasion. The blood was normal. The stools were guaiac positive twice in five determinations. The blood chemical findings showed normal vitamin C, uric acid, protein and bilirubin levels; bromsulfalein excretion was normal. The prothrombin time was 33 seconds, the normal being 20 seconds. The corrected sedimentation rate was 0.3 mm. per minute. The Congo red test showed 50 per cent remaining in the blood at one hour. Gastric analysis showed no free acid. An electrocardiogram showed, as before, a moderate left-axis deviation.

X-ray films of the joints showed progression in the pathologic process and considerable bone atrophy, especially of the shoulder girdle. Examination of the gastrointestinal tract was suggestive of esophageal varices and demonstrated a 2.5-cm. by 1.0-cm. ulcer crater in the antrum, the center of the crater lying 3.5 cm. proximal to the pylorus. The appearance was that of a benign ulcer.

The patient was started on an ulcer regime and physiotherapy. The prothrombin time having risen to 55 seconds, she was given synthetic vitamin K, with a return to 31 seconds. The gastric symptoms disappeared, but a film taken two weeks after the first showed no diminution in the size of the ulcer.

One month after admission, the patient developed photophobia, with conjunctival injection, and corneal ulcers were noted, so that she was transferred to another hospital for further care. After a week's stay, during which the keratitis did not improve, being ascribed to riboflavin deficiency, her temperature rose suddenly to 101°F., and she became slightly disorientated and incoherent. The following day, the temperature was 102°F., and she was transferred back to the medical service of this hospital.

Examination showed an acutely ill woman lying flat in bed, with labored respirations, slight cyanosis of the lips and a dry tongue. The heart and lungs were unchanged. The blood pressure was 100 systolic, 60 diastolic. The abdomen was markedly swollen, and there was sagging in the flanks. Spasm was present throughout, and compression of the umbilical hernia produced a tinkling, gurgling sound. Peristalsis was absent. The patient expired a few minutes after examination.

## DIFFERENTIAL DIAGNOSIS

DR. ALFRED O. LUDWIG: In this case, we are dealing with a woman who obviously had chronic progressive rheumatoid arthritis and several complications that might go with that disease or with its treatment. The first important statement in this history is that she took a drug containing cinchophen. It is quite well known that cinchophen occasionally produces subacute or acute yellow atrophy of the liver. Although such sensitivity is infrequent, it is important to recall that of 190 cases reported up to 1933, 46 per cent were fatal. It is probable that many cases are unreported, so that the incidence of toxicity may be much more frequent. Because of the serious nature of such reactions, we no longer use the drug in this hospital. One should remember that, as in this case, toxicity may not develop until several months after the taking of the drug, and that it may also occur with small doses, one case being reported following a single dose of 7.5 gr. This woman developed the typical clinical picture of subacute yellow atrophy, with drowsiness, ascites, jaundice and an increased bleeding tendency. During the time she was jaundiced, she apparently had a remission of the joint symptoms. This phenomenon has been previously reported, particularly by Hench\* of the Mayo Clinic, who points out that the quantity, not the quality, of the jaundice, is important. He states that a blood bilirubin level of 8 mg. or more per 100 cc. is necessary before much improvement in joint pain occurs. Such remissions may last anywhere from five weeks to one and a half years; then usually, as in this case, the joint pain returns. It is of further interest that this patient had jaundice seven years before admission and some four years before she began to take cinchophen. There is some evidence that cinchophen may be more toxic to patients who have had previous liver damage, regardless of cause.

Examination showed a slight generalized adenopathy that might very well have been a part of the rheumatoid arthritis. Adenopathy is not infrequent in rheumatoid arthritis and may also be associated with splenomegaly. I believe the fluid at the right base was secondary to the acute disturbance in the liver. It is quite common in such cases, and is probably due to irritation of the pleura over the diseased organ. The patient obviously had ascites, again secondary to the liver disease. The

\*Hench, P. S., Bauer, W., Dawson, M. H., Hall, F., Holbrook, W. P., Key, J. A., and McEwen, C. The problem of "rheumatism" and arthritis: review of American and English literature for 1938. *Ann. Int. Med.* 13:1837, 1939, 1940.

enlarged spleen was undoubtedly associated with the hepatitis rather than with the arthritis. The examination of the joints is characteristic of rheumatoid arthritis. The guaiac-positive stools are related to an increased bleeding tendency from liver disease. That is also true of her anemia and leukopenia. A lowered serum protein is quite frequently associated with liver disease, although it may also be found in long-standing cases of rheumatoid arthritis. At the time she arrived at the hospital, the acute process in the liver had subsided considerably, because the van den Bergh was normal, and the icteric index only 4. A positive Takata-Ara test confirmed the diagnosis of liver disease. This test depends on the presence of an increased amount of globulin in the blood. It is usually positive only with a severe degree of liver disease. The bromsulfalein test showed 10 per cent retention, which is also consistent with the diagnosis of liver disease. The sedimentation rate was just at the upper level of normal by our method. The patient had a somewhat low fasting sugar value, which again may be related to the liver disturbance.

I think it might be worth while to see the x-ray films.

DR. TRACY B. MALLORY: There is no x-ray man here, unfortunately.

DR. LUDWIG: In the absence of expert opinion, I shall have to limit myself to the findings in the joints. I should like to have some help in determining the character of the lesion in the stomach.

The joint findings are characteristic of chronic rheumatoid arthritis. The irregularity and narrowing of the joint spaces and the marked atrophy of the bones, with evidence of joint destruction and subchondral cysts are consistent with rheumatoid arthritis.

There were several examinations for esophageal varices, and I gather that they were thought to be present.

DR. MALLORY: Dr. Aubrey O. Hampton, on interpreting the films, thought they probably were present but could not be certain.

DR. LUDWIG: I am led to believe that they thought the ulcer was benign. Is that correct?

DR. MALLORY: It is, so far as the fluoroscopic findings and films are concerned.

DR. LUDWIG: Her marked overreaction to Nembutal and morphine is also of diagnostic value. We have observed such sensitivity to morphine in a number of patients with proved hepatic cirrhosis. In such cases, even small amounts of morphine may cause death.

The diagnostic problem here is to decide what caused death. From the history, I think we must

conclude that this patient did have toxic cirrhosis of the liver, almost certainly secondary to the ingestion of cinchophen. However, the symptoms before her last admission seem to have been due to the presence of a gastric ulcer. The laboratory examination showed an increased prothrombin time, which is consistent with the liver damage. It is of some importance that the gastric analysis showed no free acid whatever at that time. This is unusual but not unheard of with benign gastric ulcers. It may be significant that the liver decreased in size over five years.

The Congo red test showed 50 per cent retention in the blood, and the test was probably carried out as part of an investigation of the incidence of amyloidosis in rheumatoid arthritis. This complication may occur as part of the disease, usually in chronic cases of long duration or in children with the severe Still's type. A loss of 20 to 30 per cent from the blood in one hour may be considered normal. Here, the loss of 50 per cent may be significant and may mean that this patient had a degree of amyloidosis. I do not believe that the eye lesions were secondary to the rheumatoid arthritis, although iritis occurs in 5 per cent of the cases in some series. Scleromalacia perforans is occasionally seen with rheumatoid arthritis and is thought to be due to the formation of rheumatic nodules on the sclera. It is possible that vitamin deficiency played a part in this case, owing to an inability to absorb these substances normally.

The final episode is poorly described. I cannot escape the conclusion that this patient died of general peritonitis. If that is so, perforation of the ulcer would be the most likely cause; however, one would expect some history of pain. At the time she re-entered this hospital, she obviously had fluid in the abdomen. The statement that there was a tinkling sound on compression of the hernia may mean that there was also free gas in the peritoneal cavity. This would be further evidence that a viscus had perforated, in this case the stomach. The ulcer may have been malignant. The absence of free acid is slight confirmatory evidence of malignancy, and the fact that the ulcer did not decrease in size over a period of two weeks is additional evidence. I do not know how we can decide that question other than by microscopic examination. Gastroscopy apparently was not done.

Are there any other conditions that should be considered? One might think of acute hepatic failure, but I do not believe the evidence given here allows such a diagnosis. The patient did not become jaundiced again, and there are none of the other characteristic findings of acute hepatic

failure. One wonders, with the previous history of stone in the gall bladder, whether she might have had an acute cholecystitis with perforation of the gall bladder; but again the evidence does not allow us to conclude this. If a gallstone played any part, she might also have had acute pancreatitis, but again the evidence is lacking. I shall make diagnoses of chronic rheumatoid arthritis, toxic hepatic cirrhosis and an acute perforation of a gastric ulcer, with general peritonitis. Microscopically, there may be some degree of amyloid disease as well.

DR. CHARLES L. SHORT: I saw this patient several times, and I think she was once a living example, and is now a dead example, of the dangers of cinchophen—the United States Food and Drug Administration has taken recognition of the dangers of cinchophen and aminophyllin and has placed certain restrictions on their use. She was disabled for the remainder of her life following cinchophen intoxication. The fact that she developed an ulcer is of some theoretical interest because acute gastric ulcers can be readily produced in dogs that have been given toxic doses of cinchophen. In fact, it is much easier to produce an ulcer in dogs after cinchophen than it is to produce liver damage. Whether her ulcer had any relation to cinchophen is quite doubtful. I do not know of any other cases in man that have been reported.

DR. WYMAN RICHARDSON: Is it true that in your material here the incidence of ulcer and liver disease is a commoner combination than that due to chance?

DR. MALLORY: I cannot say that it is. I thought for a time that it was, but as we see more cases, such a combination does not come up very frequently.

#### CLINICAL DIAGNOSES

Gastric ulcer.  
Cirrhosis of the liver.  
Rheumatoid arthritis.

#### DR. LUDWIG'S DIAGNOSES

Rheumatoid arthritis, chronic.  
Toxic cirrhosis of the liver.  
Gastric ulcer, with perforation.  
General peritonitis.

#### ANATOMICAL DIAGNOSES

Chronic rheumatoid arthritis.  
Toxic cirrhosis of the liver (probably due to cinchophen).  
Benign peptic ulcer, with perforation.

General peritonitis.  
Pneumoperitoneum.  
Splenomegaly.  
Esophageal varices.

#### PATHOLOGICAL DISCUSSION

DR. MALLORY: Dr. Ludwig has made this very complicated case seem almost absurdly easy. The patient showed an extremely small liver, weighed only 650 gm., which was also the weight of the greatly hypertrophied spleen. Esophageal varices were present and very readily demonstrated at autopsy. There was no evidence, however, that they had bled at any recent period. There was a large ulcer in the stomach just at the edge of the prepyloric area. It measured 3 cm. in length, 1 cm. in width and 1 cm. in depth. We were very suspicious that it might prove to be malignant, and therefore cut a considerable number of microscopic sections through its margin, all of which showed a perfectly benign mucosa. We must accept it as a benign ulcer in spite of the fact that this patient showed so very little hydrochloric acid in the gastric secretions. The test was positive on only one occasion, and then weak. The final episode was a perforation of the gastric ulcer, and there was generalized peritonitis, with considerable amounts of air beneath the diaphragm, which showed up clearly on post-mortem x-ray plates. There were, of course, all the usual changes of a severe chronic rheumatoid arthritis.

A PHYSICIAN: Was there any amyloid disease?  
DR. MALLORY: No.

#### CASE 27332

##### PRESENTATION OF CASE

A thirty-four-year-old woman entered the hospital complaining of the sensation of a lump in her throat.

The patient felt well until two years before admission, when the sensation of a lump in the throat appeared just above the suprasternal notch. It was constant, felt like "a piece of apple" in the throat, and was aggravated by swallowing, although there was no difficulty in swallowing or in breathing. The symptom disappeared within three weeks but returned from time to time when the patient was overworked, tired and nervous.

Four months before admission, the sensation once again became constant and grew worse, producing slight difficulty in swallowing if food was taken too quickly. The patient stated, "The morsel seems to stick in my throat for a moment." Two months later, she saw her physician, and at

this time a constant substernal burning sensation had appeared; x-ray films of the chest were taken. Two weeks before admission, the patient stopped work, and immediately her symptoms subsided.

At no time had there been cough, hoarseness, dyspnea or weight loss. For the previous week, the patient had noticed a dull pain on movement of the left elbow, wrist and thumb. She had suffered from diphtheria and the usual childhood diseases. The family history was irrelevant.

On examination the patient was well developed and well nourished and in no apparent discomfort. The thyroid gland was palpable in the suprasternal notch during swallowing. The cardiac apex and left border of dullness were in the anterior axillary line. A blowing systolic murmur was heard at the apex and in the aortic area; the blood pressure was 120 systolic, 85 diastolic. Examination of the lungs, abdomen, pelvis and nervous system was negative.

The temperature, pulse and respirations were normal.

The urine was normal. The blood showed a red-cell count of 5,200,000 with a hemoglobin of 80 per cent, and a white-cell count of 10,600 with 67 per cent polymorphonuclears. A blood Hinton reaction was negative.

An x-ray film of the chest showed a round soft-tissue mass approximately 6 cm. in diameter behind the heart in the angle between the spine and diaphragm on the left side. The esophagus touched its anterior wall, but was probably not adherent to it. The mass did not pulsate and showed no evidence of calcification. The base of the right upper-lung field was unusually bright, the heart was normal in position, and the spine showed no abnormalities in the region of the mass.

Films taken in the upright and horizontal positions, with the patient lying on the right side, failed to show definite change in the size of the mass.

An electrocardiographic recording showed normal rhythm at 90, with a PR interval of 0.14 second. There was a tendency to right-axis deviation. T<sub>2</sub> was low, T<sub>3</sub> slightly inverted.

On the fourth hospital day, an operation was performed.

#### DIFFERENTIAL DIAGNOSIS

DR. JACOB LERMAN: The story is that of pressure symptoms in the neck of two years' duration, with a sensation of a lump in the throat, but no hoarseness and no difficulty in breathing. There is no mention of an objective pressure symptom, namely, clearing of the throat, which the patient

usually disregards. The symptoms became worse four months before entry, and in addition, difficulty in swallowing became definite. There is no mention of cough, hoarseness, dyspnea, pain in the chest or cardiac embarrassment. When the patient stopped work, the pressure symptoms subsided. On the whole, pressure symptoms in the neck fluctuate considerably, depending on such factors as nervousness, fatigue and rest.

Physical examination revealed no discomfort, and the patient was able to breathe properly. The thyroid gland was palpable, but no mention is made of its size. The description is that of a substernal gland, because when she swallowed, only the top portion could be felt.

The x-ray report fails to mention the thyroid gland. It seems that if the gland were in the position described, the radiologist should have visualized it, particularly after a swallow of barium. There is no mention of this procedure. According to the x-ray examination, the heart is not displaced by the mass in the posterior mediastinum. We should expect some deformity of the trachea, not only from the mediastinal mass but also from the goiter that was felt in the suprasternal notch. However, there is no description of the trachea.

The electrocardiogram may be unimportant, or may indicate pressure on the heart by the tumor, producing slight right-axis deviation.

The differential diagnosis boils down to some form of mediastinal tumor. The first question I should like to settle, assuming it was neoplastic, is whether it was benign or malignant. It seems from the description that the tumor was not malignant. It is described as a discrete lump, which fits in with a diagnosis of benign tumor. The absence of tissue destruction, as indicated by freedom from pulmonary infection and toxemia, and the absence of venous obstruction, involvement of the recurrent laryngeal nerve or erosion of bone argue against malignancy. Of the benign tumors, one must consider neurofibroma, fibroma, chondroma, myoma, dermoid and simple cyst.

The evidence is against aneurysm. Presumably, the aorta was visualized and found to be distinct from the mass, which did not pulsate; the blood Hinton reaction was negative. One ought to consider a diverticulum of the esophagus, which could produce such a large mass. Certainly, in this event, x-ray study should have revealed a connection between the esophagus and the mass. Also, a large diverticulum would change in appearance with change in position. It occurred to me that a large diaphragmatic hernia could produce this picture. Here, also, the radiologist would have visualized the connection between the mass and

the stomach, and the mass would have changed in size and shape with change in position.

Because of the presence of a goiter, one must consider the possibility that an intrathoracic goiter had moved down from the usual position and had gradually wandered to the bottom of the thoracic cage. Any tumor of thyroid origin that lies below the superior strait has to descend as it grows. If it descends below the level of the arch of the aorta, it can grow laterally or posteriorly. The fact that the symptoms were intermittent suggests that the mass grew intermittently. This is consistent with the growth of a portion of a substernal goiter downward into the posterior mediastinum. I am assuming that the examiner found a substernal thyroid gland. Against this assumption is the lack of pressure symptoms. I should like to know more about the x-ray appearance of the esophagus and trachea.

DR. CHARLES L. SHORT: I saw these x-ray films, and there was no sign of a substernal thyroid gland. I also examined the patient before x-ray examination was made and did not feel any goiter.

DR. LERMAN: The examiner was very explicit. Should I take his findings at their face value or be influenced by what Dr. Short has said? The position of the mass is consistent with intrathoracic goiter. I have seen similar tumors that have "plunged" into the thorax and assumed positions either lateral or posterior to the heart without producing much deformity of the adjacent organs. I shall have to consider, first, a large intrathoracic goiter and, secondly, and commoner, a benign tumor of the mediastinum, such as a neurofibroma. The x-ray report mentioned that the base of the right upper lung was unusually bright. This was probably due to compensatory emphysema of this lobe as a result of partial collapse of the right middle and lower lobes.

DR. SHORT: I saw this patient before she had an x-ray examination, and she certainly gave the appearance and the story of a patient with functional symptoms. I was rather surprised when the x-ray report of mediastinal tumor came back.

There was one interesting thing in the physical examination—the apparent displacement of the heart to the left. I think that might have given us a clue to the presence of tumor in the chest. I should be interested to know whether the heart was actually displaced. The murmur was not enough to make a diagnosis of organic mitral regurgitation. The x-ray films that I saw were even more confusing, because the tumor mass

was first interpreted as being cystic, the most probable diagnosis being a congenital cyst of the lung. On the basis of that and of the patient's story, it seemed unlikely that the mass was causing symptoms. I was rather hesitant about advising operation without having a period of observation, but she had the tumor removed.

DR. LERMAN: There is nothing here to indicate that the heart was displaced. It was normal on x-ray examination.

DR. SHORT: Yes; but on physical examination, the apex was clearly palpable outside the mid-clavicular line.

DR. LERMAN: Did you mean displacement anteriorly?

DR. SHORT: I just said displacement. I suppose it was anterior rather than to the left, but the apex was certainly felt outside the mid-clavicular line, and in the absence of intrinsic heart disease, I should assume that there was some mass in the mediastinum displacing the heart.

DR. EDWARD D. CHURCHILL: This case, like others we have recently discussed, shows the chaotic state of the interpretation of symptoms arising from mediastinal tumors, and is characteristic of those of a very large number of patients. The symptoms seem completely removed from anything that this tumor could possibly have done and so remote, as Dr. Short has intimated, that one might be entirely convinced that they have nothing to do with a mediastinal tumor. I think that is often so. Frequently, as in this case, we have not been at all convinced that the mediastinal tumor has had anything to do with the symptomatology; yet the patients must be treated. There are sensations that do arise from tumor in the mediastinum, and patients not infrequently have great difficulty in finding words to express just what they are experiencing. It is not pain; it is not oppression; it is not covered by the usual words that doctors use to describe sensations. Or we ask them these questions, and they say, "No," but they eventually find a word for it. The result is that I have seen patients with malignant tumors of the mediastinum carried on for long periods as neurotics simply because they could not express what they were experiencing. I think the decision to operate must be based on the frustration and impossibility of knowing what type of tumor one is going to find and what that tumor is going to do for the next few years.

#### CLINICAL DIAGNOSIS

Neurofibroma of mediastinum.

## DR. LERMAN'S DIAGNOSES

Intrathoracic goiter or mediastinal neurofibroma.  
Partial collapse of right middle and lower lobes.

## ANATOMICAL DIAGNOSIS

Neurofibroma of mediastinum.

## PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: This patient was explored, and a fibromatous tumor that apparently arose from the sympathetic chain was found. It lay just above the diaphragm and lateral to the aorta. It had pushed the lower lobe forward and had produced partial collapse. Histologically, it was a fibromatous tumor, with some areas of what we call "palisading," which suggest a neurogenous origin. It also showed extensive areas of xanthomatous degeneration, large parts of the tumor being bright yellow. On histologic examination, these yellow areas were composed largely of mono-

nuclear phagocytes containing cholesterol, similar to those found in atheromatous plaques. The diagnosis of neurofibroma is not open to any question.

DR. RALPH ADAMS: This patient was well from the time of operation, two years ago, until last fall. At that time, she was seen because again she had the sensation that a morsel was sticking in her throat, and she complained of nervousness, irritability and difficulty in swallowing. These symptoms had been precipitated by the persuasive arguments of a young man who wished to marry her. X-ray films were negative, and she was reassured about her general condition.

DR. LERMAN: Was there any comment at operation about where the thyroid gland was located?

DR. MALLORY: I do not think they got anywhere near it. The operative incision was low and posterior?

DR. CHURCHILL: Yes; it was well down.

## PREVENTIVE GERIATRICS

THE paper covering the potentialities of preventive geriatrics that appears in this issue of the *Journal* will have something of an emotional appeal to all but our youngest readers, for it embodies an outlook on advancing years that is generally cherished in middle age. That for which we all fondly hope as we reach the climacteric presents a pleasant prospect and makes good reading, even though we know it cannot be attained by all. That it may become more generally attainable, however, is not entirely a wistful hope but a reasonable, and perhaps even a scientific, goal for which to strive. Just as pediatrics has thrived on the irresistible urge of the baby to grow up, so may geriatrics promote itself by husbanding the natural involutional processes that tend to adjust

and protect the earthly tabernacle against the ravages of time.

It is to be hoped that this promotion will not be forced, as it sometimes has been in political discussions that have moved along parallel lines. Much more knowledge of the physiology of age—here called gerontology—is needed before we can know how to improve our present habits. The conviction that they are not the best possible habits has long been entertained and expressed, as by Lord Rosebery:

It is a black moment when the heralds proclaim the passing of the dead, and the great officers break their staves. But it is sadder still when it is the victim's own voice that announces his decadence, when it is the victim's own hand that breaks the staff in public. I wonder if generations to come will understand the pity of it!

It is to be hoped that statistical data will be carefully interpreted. With the rapidly increasing numbers of older people, as well as with our changing community and family habits, it is going to be easy to quote figures that, if they are not carefully interpreted, may become the basis of ill-advised public action. Decreases in death rates are bound to be balanced by subsequent increases in other categories of the *International List*. Part of these increases must therefore be counted as compensating phenomena, and reckoned among the current landmarks of the constantly changing scene. The years of our lives are still approximately three score and ten. We have not increased the natural span; we have merely prevented infectious and metabolic accidents from snuffing us out prematurely.

It is to be hoped that gerontology may set a stage upon which a rational concept of aging processes will develop. Too often, in the past, we have been tempted by such plausibles as medical glandular and surgical rejuvenation. What has become of the operations of Voronoff and Steinhach? Such devices will fail for the same physiologic reason that Ponce de Leon failed in his quest for the Fountain of Youth. We badly need a basic science on which to build. For gerontology the field is open.

Lastly, it is to be hoped that practitioners of preventive geriatrics will not rush to establish for themselves examining and qualifying boards. None who is not a competent general practitioner can hope to become a competent geriatrician, and the time has come when a specialty for the general practitioner could have a salutary effect on medical values. Who better than the general practitioner could guide us across the falling ground and down into the valley? Those must be the years when the individual and family and community backgrounds will mean the most; those have been the years when the family doctor has served the best—let him now perfect himself. He is apter to have known us through all the seven ages described by the melancholy Jacques, and such knowledge is destined to be an important part of geriatrics.

And so from hour to hour we ripe and ripe,  
And then from hour to hour we rot and rot,  
And thereby hangs a tale

## UNITED CHINA RELIEF

THE Medical Division of United China Relief has announced the appointment of Dr. Co Tui as medical adviser to the China Defense Commission, which is in charge of all purchases for the Chinese government under the terms of the Lease Lend Act. A total of \$228,721 has been allocated for medical and relief supplies to free China; this sum was collected through the Bowl of Rice parties in California and through the tireless efforts of the national committee of United China Relief and the China Emergency Relief Committee. Dr. Co Tui, with the advice and help of leading American surgeons and physicians, will co-ordinate requests for medical provisions from medical experts in China and will help decide which supplies will most effectively meet Chinese needs.

The tremendous program of medical relief calls attention to facts that are frequently overlooked in the campaign of all out aid to Britain. China, too, has for years been resisting the aggression of an Axis power, and the Chinese government and

people deserve the fullest possible aid from the democracies. All-out aid to China is a contribution to the front line of American defense, medical aid to China will carry sorely needed relief not only to the inhabitants of Chungking, the most thoroughly bombed city in the world, but also to the millions who fight ceaselessly by day and night for the preservation of their country and the vindication of their national honor.

## MEDICAL EPONYM

### JARISCH-HERXHEIMER REACTION

Professor O Jarisch (1850-1902), of Graz, discussing "Therapeutische Versuche bei Syphilis [Therapeutic Experiments in Syphilis]" in a series of articles, writes as follows in his first installment, in the *Wiener medizinische Wochenschrift* (45: 721-724, 1895)

The following experiments were based on an observation that has certainly been made previously by many syphilologists, but has never to my knowledge been taken account of. I refer to the observation of a kind of reaction that shows itself in the first few days of a course of mercury inunctions in patients with syphilitic roscolae as an exacerbation of the topical phenomena of the disease. After from two to five inunctions or injections, the individual spots often become more distinct than before, and thus seem to be increased in number. This exacerbation of signs ends in an involution that, it seems to me, corresponds in rapidity to the intensity of the reaction.

If, as indicated by numerous facts, the effect of mercury in syphilis is not due to a supposed direct antiparasitic effect, the preceding fact must suggest the conception that mercury has an (indirect ?) chemotactic, inflammatory effect analogous to tuberculin and the bacterial proteins.

Dr. Karl Herxheimer (b 1861), chief physician of the Skin Department of the Municipal Hospital in Frankfurt am Main, and his assistant, Dr. Krause, contributed a paper, "Ueber eine bei Syphilitischen vorkommende Quecksilberreaktion [A Mercury Reaction Occurring in Syphilitic Patients]," in the *Deutsche medizinische Wochenschrift* (28: 895-897, 1902). A portion of the translation follows:

Some years ago, one of us observed striking changes in the exanthem of syphilis after the administration of mercury. More than a year ago, we made a similar observation of a patient suffering with a macular syphilide, which renewed our interest in the subject. The exanthem had changed to such a degree within about twenty four hours after an initial inunction of 40 gm of gray mercury ointment that no characteristic of the original efflorescent, either of size, form or color, remained. The lesions were larger, had become elevated above the surface of the skin, had taken on

a bright-red color, and had rather the characteristics of an eruption of erythema exsudativum multiforme. After twenty-four hours, however, it had completely disappeared. . . . After we had observed the reaction in more than 60 cases and were in a position to study it, we believed that we could describe it as follows: It appears, as has been said, when a sufficient amount of mercury is completely absorbed for the first time. . . . If there is any single, distinctive feature of the phenomenon, it is the change in the syphilitic exanthem from a typical to an atypical form. . . . From what has been said, it seems justified to consider this a "reaction." This is developed by an oversensitiveness of the cell, which has been affected by syphilis toward mercury in such a way that mercury, by uniting with the cell, causes increased damage.

## MASSACHUSETTS MEDICAL SOCIETY

### SECTION OF OBSTETRICS AND GYNECOLOGY\*

#### CESAREAN SECTION AND PNEUMONIA FOLLOWED BY DEATH

A thirty-two-year-old para II presented herself at a surgeon's office desiring a cesarean section. She stated that she was at term. Her desire for operation was based on unpleasant memories of the first labor and operative delivery, which the baby survived. Apparently no attempt was made to ascertain the history of the first pregnancy.

The past history was irrelevant, and the prenatal care during this pregnancy had been inadequate. Cesarean section, performed on a date set by the patient, was by the low-transverse cervical route. She was etherized by a nurse, and there is no indication in the history of how the anesthetic was taken. Death occurred nine days later, apparently because of a postoperative pneumonia. There was no autopsy.

*Comment.* This case is reported solely to emphasize the seriousness of needless cesarean section. Any laparotomy carries certain hazards, and even in the hands of trained anesthetists, pneumonia may cause death. A physician who does not appreciate this possibility is remiss in his obligations to his patients. In this case, there was no obstetric indication for cesarean section, and death should be attributed to lack of medical honesty.

\*A series of selected case histories by members of the section will be published weekly. Comments and questions by subscribers are solicited and will be discussed by members of the section. Letters should be addressed to Dr. Raymond S. Titus, Secretary, 330 Dartmouth Street, Boston.

## CORRESPONDENCE

### "ACCOUCHEMENTS FOR AMERICA"

*To the Editor:* We Americans are divided about many things, but interventionists and isolationists are agreed on one thing at least, and that is that America must prepare to defend itself. We hear cries for speeding up of manufacture of all sorts of vehicles and weapons of war. We are told that we need more ships, more tanks, more aeroplanes. I have as yet heard no one mention the fact that we shall need more young men to sail the ships, drive the tanks, fly the aeroplanes. In other words, America also needs more babies! Instead of other true slogans, it might be well for American women in the position to do so to take "Accouchements for America" as their slogan. If Germany wins the war and proceeds to utilize the shipyards and other resources of Europe,—perhaps for an attack on this country,—it may mean that 1960 will be the year when our country's fate is at stake. In my opinion, we should do long-range thinking, and attempt to increase our potential army of that time right now. If our birth rate can be increased, we may be able to keep our place in a world that sees the dictators making frantic efforts to increase their populations.

We should not allow the so-called "newer races" to carry our burden in 1960. Most of these people have large families and are having their deliveries cared for by clinics. Apparently few of the wealthy, who can afford an unlimited number of children, are desirous of large families. I believe that physicians should co-operate to encourage large families among the other class—that is, the great independent, bill-paying middle class. In the last few years, hospitalization plans have helped.

We may soon have such things as a bachelor tax and subsidies given to young people to allow them to be married early. My reason for writing this letter is to suggest that we get the jump on the rest of the country and start the ball rolling by offering a definite plan to encourage new citizens.

The plan is as follows: each physician will announce to his patients that each couple's fourth delivery will cost only 75 per cent of the third; the fifth delivery 75 per cent of the fourth and so forth. For example:

Fee for third baby	\$100
Fee for fourth baby	75
Fee for fifth baby	55
Fee for sixth baby	40
Fee for seventh baby	30

Those who object to this plan on the grounds that the fee is not commensurate with the time and trouble expended on the case should consider the service a patriotic duty, and reflect that, at the present time, innumerable French physicians would gladly accept even more burdensome conditions if France could be once again a strong, free, prosperous and happy nation. Incidentally, this movement will be an investment in good will, which will mean a great deal for our profession when the now apparently providentially postponed battle for socialized medicine is again commenced in the postwar period.

## A STANDARD ELECTROENCEPHALOGRAPHIC TECHNIC FOR THE LOCALIZATION OF GROSS INTRACRANIAL LESIONS\*

FREDERIC A. GIBBS, M.D.,<sup>1</sup> DONALD MUNRO, M.D.,<sup>2</sup> AND WALTER R. WEGNER, M.D.<sup>3</sup>

BOSTON

SINCE Walter<sup>1</sup> first reported his technic for the localization of intracranial lesions by electroencephalography, ample evidence<sup>2-8</sup> has accumulated to prove beyond question its value as a supplement to previously available methods. The present report describes and gives the results obtained with a standardized and simplified technic, which, it is believed, makes electroencephalographic localization a more practicable clinical procedure. Except for a master selector switch, which will be described later, the required apparatus is the same as that used by Williams and Gibbs.<sup>4, 6</sup>

### APPARATUS

The apparatus consists of three channels of undistorted amplification of all frequencies from 1 to 1000, with a voltage intensification of approximately ten million times, a noise level of less than 5 microvolts, and three ink writing oscillographs that record without distortion up to 80 cycles per second. The amplifiers should be so designed that they are independent of each other, that is, the signals on one channel should not affect the signals on either of the other channels.

One of us (F. A. G.), in previous reports with Williams,<sup>4, 6</sup> subscribed to the use of cotton pledget electrodes wet with salt solution and held on the head with elastic bands. Such electrodes have the great advantage of being easily placed in any desired combination of positions, but they are so liable, by shifting and drying, to produce artifacts resembling the disorder produced by a tumor that it seemed hazardous to use them in ordinary clinical practice. If the type of electrode introduced

by E. L. Gibbs is used, electrode artifacts can be greatly reduced or eliminated. Such electrodes are made by flattening a solder pellet on the end of a fine (34 gauge) enameled wire. This can be done by thrusting the bare end of the wire into a heated drop of solder and pressing on the drop while still hot. The flattened pellet should form a disk about 1 or 2 mm thick and approximately 5 mm in diameter. Contact with the scalp is made by covering one side of the electrode with a saline paste (Sanborn electrode paste). A detailed description of the precautions to be taken in applying such electrodes is given elsewhere.<sup>9</sup>

In localizing intracranial lesions, it is desirable to cover all accessible surfaces of the brain with electrodes. As a practical compromise, sixteen leads are sealed to the scalp and forehead, all more or less equidistant from each other (Fig. 1). They are arranged in four longitudinal columns in such a way that the first column, referred to as A, starts with Electrode 1 slightly anterior to the right temple; Electrode 2 is placed over the right inferior precentral area, Electrode 3 over the right inferior postcentral area and Electrode 4 halfway between the third and the right occipital pole. The next column, referred to as B, has Electrode 1 half way between the upper and lower limits of the forehead and directly over the pupil; Electrode 2 is in the right precentral region, about two thirds of the way from the mid line to Electrode 2 in Column A, Electrode 3 in the postcentral area about two thirds of the way from the mid line to Electrode 3 in Column A, and Electrode 4 slightly to the right of the occipital pole. Column C is the left hemisphere equivalent of Column B, and Column D is the left hemisphere equivalent of Column A.

Each electrode is connected by its 34 gauge enameled wire lead to a separate binding post on a

junction box. The junction box is equipped with a master selector switch designed and constructed by A. M. Grass. By means of this switch, it is

and by Williams and Gibbs.<sup>5</sup> Slow waves such as are seen around an organic lesion are more or less sinusoidal and very often have some normal ac-

FIGURE 1. Diagrams Showing the Position of the Electrodes.

The diagram at the upper left shows the arrangement of electrodes on the schematized surface of the head, considered as a rectangle, with electrodes arranged in four equidistant columns, A, B, C and D, of four electrodes each and in four equidistant rows, 1, 2, 3 and 4, of four electrodes each. The other diagrams show the concessions that are made to the curved surface of the head in actual practice. The arrangement of the columns and of the rows is kept as nearly like the rectangular scheme as possible. The position of each electrode is described in the text.

possible to connect the amplifiers to any four electrodes, longitudinal or transverse, as shown in Figure 2.

#### CRITERION FOR LOCALIZATION

The criterion used for localization of gross organic lesions is that described by Walter,<sup>1</sup> namely, apparent reversal in phase of waves with a frequency of approximately  $\frac{1}{2}$  to 3 per second. Waves off this frequency Walter calls "delta waves." A region showing the maximal number and voltage of such waves (indicated by out-of-phase relations) he calls a "delta focus." Good illustrations of such foci are shown by Walter

and by Williams and Gibbs.<sup>5</sup> Slow waves such as are seen around an organic lesion are more or less sinusoidal and very often have some normal ac-

tivity superimposed on them. In general, the severer the lesion, the less the superimposed activity, the slower the waves and the higher their voltage. Extraneous voltage fluctuations, which might be confused with the slow waves from around a gross lesion, are discussed elsewhere.<sup>9</sup>

It is important to recognize at the outset that the apparatus cannot distinguish accurately between different types of lesion and that it cannot localize deep cerebral and subtentorial lesions. Smith and his co-workers<sup>10</sup> have said that subtentorial lesions can be localized with the electroencephalogram, but this is qualified to mean that

cases with cerebellar tumors show slow-wave foci in the occipital cortex. In our experience, such foci are usually lacking. Certain wave formations are commonly encountered in epilepsy. These have been discussed and illustrated elsewhere.<sup>3</sup> As pre-

FIGURE 2 Schematic Diagram of the Manner in Which the Electrodes are Connected

By turning the dial on the master selector switch to any one of the indicated positions, A, B, C, D, 1, 2, 3 and 4, it is possible to connect the corresponding column or row to the amplifiers. When turned to a column (as shown by the dotted lines), Electrodes 1 and 2 go to Channel 1, Electrodes 2 and 3 to Channel 2, and Electrodes 3 and 4 to Channel 3, when a row is connected (as shown by the solid lines), Electrodes A and B go to Channel 1, Electrodes B and C to Channel 2, and Electrodes C and D to Channel 3.

viously stated, they are not generally satisfactory for localizing gross disease. However, any focus of epileptic discharge should be noted, for its presence and position—when taken with the rest of the clinical and laboratory evidence—may be a valuable diagnostic clue.

If a focus has been localized to the region under one electrode, the electrode should always be replaced with another close to it to make sure that a bad contact is not producing the slow waves.

If a focus cannot be detected with the primary

placement of electrodes, and if the clinical signs point to a specific area, all sixteen electrodes should be placed so that they form a square covering and extending beyond the presumable site of the lesion.

When the electroencephalographic localization is the sole or chief reason for contemplating surgical exploration of a particular area, it should be repeated on a subsequent day, with the sixteen electrodes concentrated around the region in which the focus was previously localized, to make sure that the focus is still there and to delineate it more sharply.

By concentrating the electrodes in a particular area, it is possible to get the maximum accuracy

TABLE 1. Results of Electroencephalographic Examination of 144 Patients Suspected of Having Operable Intracranial Lesions

RESULTS	No. OF PATIENTS

obtainable with electrodes placed on the outer surface of the skull. Grinker and Serota<sup>11</sup> have used electrode placements on the inferior surface of the cranium, and Jasper<sup>12</sup> has employed these electrode placements for localizing tumors. In certain cases, these so-called "nasal electrodes" may give important evidence. At any rate, the inferior surface of the brain is of interest in many clinical problems and should not be disregarded. However, temporal lobe tumors and tumors arising from the sphenoidal ridge can be localized with electrodes on the outer surface of the head. For clinical studies, it seems best to attempt first a localization with the sixteen electrodes covering the outer surface of the head and later, if additional evidence is required, to use special electrode placements, which are adjusted to the exigencies of the particular situation.

## RESULTS

The results of the electroencephalographic examination of 144 patients suspected of having gross intracranial lesions are shown in Table 1. In 33 patients with lesions found at operation, the neurologic examination led to a correct localization in 64 per cent, a ray study without air in-

jection in 21 per cent, x-ray study with air injection in 39 per cent and electroencephalography in 82 per cent.

The poor score for air injection followed by x-ray examination is not owing to any inaccuracy of the procedure but merely to the fact that because of discomfort to the patient, danger or expense, it was not used in the majority of cases. The true accuracy of the method appears when one considers the 14 cases in which it was used; it led to a correct localization in all except one case, that is, it was 93 per cent accurate. In the 10 cases in which no lesion was found at operation, a localized lesion was indicated by the neurologic examination in 7, by x-ray study without air injection in 2, by x-ray with air injection in 5 and by the electroencephalogram in 5.

### DISCUSSION

It is unlikely that any electroencephalographic method of localizing space-consuming lesions will give results as good as x-ray study with air injection, for the latter gives almost direct evidence of the lesion. On the other hand, electroencephalography is painless, without danger and relatively cheap, so that there is no reason why it cannot be used on all cases. It should be regarded as a special type of neurologic examination, which has the following advantage over the ordinary neurologic examination: it can test the functional activity of various cortical areas that are clinically silent. In the cases in this series that had gross supratentorial lesions, electroencephalography was more useful than urologic examination for localization. The comparative values and different methods of localization are discussed here to show how useful electroencephalography is in terms of other techniques now commonly employed, not with the idea that any of the latter should be abandoned. Ac-

curate localization of differently situated lesions of various types require the use of all available methods. Each method contributes to the total accuracy.

### SUMMARY AND CONCLUSIONS

A standardized and simplified form of Walter's technic for the localization of gross intracranial lesions is described, and the results obtained with it on a series of 144 patients suspected of having an expanding intracranial lesion are given. Of the 98 patients discharged because of insufficient evidence of an operable lesion, 85 per cent showed no electroencephalographic evidence of localized gross disease. Among the 44 patients operated on, electroencephalography gave correct localizations or correct negative findings in 73 per cent. In the 30 cases in which the lesion involved the cerebral cortex, localizations were accurate in 90 per cent.

The technic described is useful for providing evidence of the presence or absence of gross cortical lesions and for localizing such lesions.

## TEMPORAL ARTERITIS\*

LYMAN H. HOYT, M.D.,† GEORGE A. PERERA, M.D.,‡ AND ABRAHAM J. KAUVAR, M.D.‡

BOSTON

UNTIL recently, the diagnosis of arteritis has been made in most cases by the pathologist. For this reason, the impression was gained clinically that all cases of arteritis and periarteritis were necessarily fatal. More careful observation of the superficial vessels has shown that arteritis and periarteritis are not only commoner and more widely distributed than was formerly believed, but that, in addition, the prognosis in certain types is distinctly favorable. During the last few years, arteritis of the superficial temporal vessels has emerged as a distinct clinical entity in which the prognosis is entirely favorable, even though the pathologic changes are indistinguishable from other types of arteritis. It has therefore seemed appropriate to report the cases of 3 patients who recovered from acute temporal arteritis, the diagnosis having been proved by biopsy.

## CASE REPORTS

**CASE 1.** M.B., a 58-year-old married woman, entered the hospital on July 2, 1940. She had been well until 3 weeks before admission, when she developed a severe headache along the right side of the forehead, the pain going down the right side of the neck. The pain soon spread to involve both sides of the head and neck, extending up to the top of the head and across the forehead. There was also a severe pain behind the eyes, and a marked paresthesia of the scalp, so that it was impossible for the patient to comb her hair. The past and family histories were noncontributory.

Physical examination on admission to the hospital revealed tenderness over both temporomandibular joints. It was impossible for the patient to open her mouth completely. There was some redness of the throat, the anterior pillars being more inflamed on the right than on the left. Small deep cervical lymph nodes were palpated on both sides, but no other lymphadenopathy was noted. There was exquisite tenderness over the temporal arteries on both sides. The heart, lungs, abdomen and reflexes were normal. The temperature was 101°F., the pulse 80, the respirations 20, and the blood pressure 118/62.

Laboratory examinations revealed negative blood Wassermann and Hinton reactions. The urine was normal. During the patient's 35 days in the hospital, the temperature varied from 98 to 103°F., with a tendency toward an afternoon rise. The white-cell count varied between 10,000 and 20,000, the majority of counts being approximately 14,000. Differential counts revealed 76 to 80 per cent neutrophils; the highest eosinophil count was 4 per cent, noted on only one occasion. The sedimentation rates were 62 and 70 mm. in 1 hour by the Wintrobe

method, the normal rate being 20 mm. The uric acid and nonprotein nitrogen levels of the blood were within normal limits. Agglutination tests for typhoid fever, paratyphoid (A and B) fever, brucellosis and tularemia and a sheep-cell agglutination test were negative, as was a gonococcus complement-fixation test.

Because of the possibility of meningitis, at the time of admission, a lumbar puncture was performed; the spinal fluid showed normal dynamics and pressure readings, a protein of 20 mg. per 100 cc., and 1 cell per cubic millimeter.

During the patient's stay in the hospital, she developed marked tenderness and induration over both temporal

FIGURE 1. Photograph of Biopsy Specimen.

*This section shows the thickened wall and the narrowed lumen of the artery from Case 1 (eosin-methylene-blue stain,  $\times 55$ ).*

arteries, but no nodules. The severity of the tenderness changed from day to day and varied on both sides, as did the swelling over the temporomandibular joints. The frontal headache persisted, but could be alleviated by pressure over the temporal artery on either side. Codeine, morphine, Nembutal and phenacetin were used for temporary alleviation of the pain, but were not effective. On the 19th hospital day, sulfapyridine was begun, was continued for 4 days, and was discontinued because of marked nausea, vomiting and generalized discomfort. A free-sulfapyridine level of 7.4 mg. per 100 cc. was obtained, but there was no change in the patient's general condition or symptomatology.

On the 28th hospital day, a biopsy of the right temporal artery was performed under local anesthesia. On gross examination, the section showed some inflammation around the site of the temporal artery, and the artery

\*From the Medical Clinic of the Peter Bent Brigham Hospital

†Associate in medicine, Peter Bent Brigham Hospital

‡Assistant resident physician, Peter Bent Brigham Hospital

appeared indurated. The pathological report was as follows:

The lumen of the vessel is diminished in caliber as a result of proliferation of the intima [Fig. 1]. The lumen is elongated, slender and lined by a single layer of endothelium, beneath which there is a large amount of fibrous tissue without inflammatory cellular infiltration. The internal elastic membrane is somewhat fragmented, but is not reduplicated. Within the muscular coat, chiefly in the internal longitudinal layer and in the outer circular layer of the media, but extending also into the adventitia, there are many small foci of cells resembling those of a granulomatous lesion. This area displays a central necrosis, with fibrinoid degen-

FIGURE 2. Photograph of Biopsy Specimen.

*This section shows a giant cell and the inflammatory infiltration in the wall of the artery from Case 1 (eosin-methylene-blue stain,  $\times 640$ ).*

eration. There are numerous multinucleated giant cells and large monocytes at the periphery of the section [Fig. 2]. In addition to these monocytes, the peripheral zone shows many lymphocytes mingled with some eosinophilic leukocytes and a few neutrophilic polymorphonuclear leukocytes. Careful search with various stains failed to reveal any micro-organisms. There is some increase in the fibrous tissue of the adventitia, and the smaller vessels in the surrounding fat are congested. Otherwise the fat and the striated muscle about the vessel are not remarkable.

The lesions in this vessel correspond to those described in cases of so-called "periarteritis nodosa" of the temporal artery. In our opinion, however, they bear more resemblance to the lesions in thromboangiitis obliterans (Buerger's disease) than they do to periarteritis nodosa.

Within a few days following the biopsy, the headache, paresthesia and tenderness were relieved, but the elevated temperature, increased sedimentation rate and leukocytosis persisted. The patient was discharged shortly after the biopsy was performed, and at present is symptom free. The blood counts and the temperature are normal.

The sedimentation rate, although still elevated, shows a tendency to be lower.

CASE 2. H.M., a 61-year-old widow, entered the hospital on April 20, 1939. Her complaints at that time were pain in the shoulders, hips, knees and back of 3 weeks' duration, and pain, swelling and tenderness around the temporomandibular joints of 2 days' duration. She also complained of severe generalized throbbing headache of about 3 weeks' duration. The past history and the family history were noncontributory.

When the patient entered the hospital, the temperature was  $100^{\circ}\text{F.}$ , the pulse 82, and the respirations 20. The blood pressure was 130/80. Physical examination revealed that the mandibular joints were tender, and that motion was limited by pain and swelling under both jaws. There was swelling of the lymph nodes in both submaxillary areas, but no other lymph nodes were enlarged. There were slightly red, indurated and tender areas over both temporal arteries. Pressure over the temporal arteries relieved the generalized frontal headache.

The blood Wassermann and Hinton reactions were negative. The urine was clear, and showed no albumin, sugar or casts. The white-cell count varied from 12,600 to 14,000, with 80 per cent neutrophils. Three per cent eosinophils were recorded on one occasion. Blood culture was negative. A skin test for tuberculosis with purified protein derivative of the first strength was negative. The basal metabolic rate was +12 per cent. The icteric index and an electrocardiogram were normal.

During the course of the illness, the patient remained comfortable on large doses of acetylsalicylic acid. The temperature varied from  $99$  to  $101^{\circ}\text{F.}$  The patient received a course of sulfanilamide for 8 days, during which she developed a marked gastrointestinal upset and an anemia. The red-cell count fell to 2,700,000. However, no essential change in the headaches or febrile course was noted. X-ray examination of the spine showed a moderate degree of arthritis.

On the 27th hospital day, a biopsy of the right temporal artery was taken. Microscopic examination of the section was reported as follows:

The artery shows marked chronic inflammation in all its coats. It is surrounded by chronic granulation tissue in which well-developed capillaries are seen, and in which proliferating fibroblasts are scattered from place to place. The entire area is densely infiltrated with cells that are predominantly lymphocytes, with a large number of monocytes, scattered polymorphonuclears, a rare eosinophil and occasional multinucleated cells that might be designated giant cells. A few lymphocytes extend into the muscular coat, separating the muscle bundles. The muscular coat is slightly thinned, and throughout its margin there are irregularly shaped masses of basophilic material, presumably fibrin. The intima is composed of proliferating connective-tissue cells, and only a minute lumen remains.

The headache disappeared to some extent after biopsy, but the patient was still febrile when she was discharged on the 32nd day.

A follow-up examination a year later revealed that the patient's elevated temperature and headache had almost completely disappeared, but she still complained of pain in the shoulders, hips, knees and back.

CASE 3. P.N., a 67-year-old store manager, was seen in the Out-Door Department on September 26, 1939. At that time, he complained of soreness and muscular aches

all over his body of 3 months duration. The patient also complained of generalized headache, pains around the mandibular joint and down the sides of the neck of 3 months duration.

The past history was significant in that the patient had had asthma presumably on an infectious basis for 5 or 6 years before this visit.

Physical examination revealed both temporal arteries to be enlarged and painful. The temperature was 98°F, the pulse 72, and the blood pressure 195/100. The rest of the examination was not remarkable. Without being referred into the hospital, the patient was anesthetized locally, and a partial excision of the left temporal artery was performed. The pathologic description of the section was as follows:

There is marked reduction of the lumen owing to intimal proliferation. Peripherally, the intima tends to be of a collagenous character whereas centrally it is more cellular and fibroblastic. A few lymphocytes and eosinophilic leukocytes are present throughout the intima. The internal elastic membrane is prominent. At some levels it completely surrounds the lumen, and at others it becomes imperceptible in an area of fibroblastic proliferation and inflammatory cell reaction. Throughout most of the circumference of the artery the normal parallel architectural arrangement of connective tissue and smooth muscle fibers of the media is well preserved. In some areas this arrangement is obliterated by an intense lymphocytic infiltration accompanying which there is a marked multinucleated giant cell reaction.

Postoperative recovery was uneventful.

When the patient was last seen, 1½ years later the headache and pain around the mandibular joints had practically disappeared.

### DISCUSSION

Historically, acute temporal arteritis has been mentioned in the literature since 1931. At that time, Horton, Magath and Brown<sup>1</sup> published a report of 2 cases. Since then, 16 additional cases have been reported.<sup>2-8</sup>

There is considerable similarity between the cases reported in the literature and our 3 cases. All the 19 patients reported have been elderly people, ranging in age from fifty-five to eighty years. The majority of the patients have been women. The presenting symptom is usually a severe, boring ache referable to both sides of the head, although usually severer on one side than on the other. The pain also seems to be severer at night, so much so that it prevents the patients from sleeping. In our experience, the headache is so intense that it is unrelieved by morphine or barbiturates. The temporal regions and temporal arteries may be tender, and during the course of the illness, the vessels may become enlarged, tortuous and surrounded by areas of hyperemia. Tenderness of the scalp and painful mastication may also be present—particularly prominent features in Case 1. In addition to the headache, the patient may complain of severe generalized symp-

oms. These patients often present the appearance of being severely ill, entirely out of proportion to the amount of local disease present. It is possible that the inflammation of the temporal artery is but a local manifestation of a more widespread disease.

The pathologic findings of the cases reported above are similar to those previously described. The general lesion is one of chronic periarteritis and arteritis. There are areas of granulation tissue in the adventitia of the blood vessels that suggest granuloma. There is an infiltration of round cells in the adventitia around the vasa vasorum, and to a marked extent in the media of the vessels. There may be a complete necrosis of the media, which is sometimes replaced by a granulomatous type of lesion. In all the cases in the literature and in our own cases, giant cells were present, and this seems to be a most constant factor. The lumen may be reduced in size, and nodular areas may appear along the outer aspect of the vessels.

From a practical standpoint the most effective treatment seems to be the removal of a segment of the temporal artery. This has been demonstrated in the 3 cases presented, and in 4 other cases in the literature.<sup>3,4,7,8</sup> After section of the artery, the headache is relieved, even though the fever and generalized symptoms may continue for as long as several weeks. It has been suggested that section of the artery severs the sympathetic nerve fibers<sup>6</sup> and in this way eliminates the pain although it is difficult to explain the ultimate relief of generalized symptoms with this treatment. It is worth noting that, in Cases 1 and 2, pressure over the temporal artery reduced the severity of the headache. This may be a point in determining whether section of the artery is going to be beneficial.

Because of the extreme practical importance of an accurate diagnosis before biopsy is undertaken, other common causes for the severe symptoms should be differentiated. First, there are intracranial causes such as brain tumor and meningitis and secondly, extracranial causes, such as phlebitis of the scalp veins, osteomyelitis of the malar and temporal bones, sinusitis, subcutaneous infection and herpes zoster. Biopsy of the temporal artery is justified in a patient with headache, fever, malaise, exquisite tenderness over the temporal artery and no other evidence of disease.

The cause of this localized arteritis is not known. Thromboses of the vasa vasorum might be an explanation,<sup>9</sup> but the reason for thromboses in this area is not apparent. Bacteriologic studies have been negative in all biopsy specimens. The fact that the pathologic specimens demonstrate

and 700 cc. of dark-red blood aspirated. Three weeks later, a second thoracentesis yielded 600 cc. of dark-amber sterile fluid. The operative wounds healed by primary union. During the 5th week of the patient's illness, the temperature hovered about 101°F. but dropped to normal within 48 hours after a third thoracentesis, which yielded 900 cc. of clear, yellow sterile fluid. The subsequent course was uneventful, the patient being allowed out of bed on the 45th day and discharged on the 50th day.

X-ray studies of the chest taken on admission and subsequently on the 1st, 4th, 12th, 19th and 21st days post-operatively revealed progressive changes consistent with the accumulation and resorption and aspiration of the pleural fluids.

Electrocardiograms were taken preoperatively (Fig.

1), during the operation (Figs. 1 and 2, B-M) and post-operatively (Fig. 3). The findings are discussed below.

*Q wave.* Tracing A reveals a deep Q wave in Lead 1. Beginning with a depth of 3 mm., it reaches a depth of 6 mm. in Tracing F, at the time of entering and aspirating the pericardial sac. The Q wave then recedes to a depth of 2 mm. when the chest cavity was finally closed (Tracings L and M). Subsequently, it remained between 1 and 2 mm., but was no longer 25 per cent or more of the main deflection. No other leads at any time showed an initial downward deflection.

*Electrical axis.* At the time of operation, when the deep Q wave was present (Tracing F), a right ventricular preponderance is noted. Subsequently, the deviation of the electrical axis became normal.

*P wave.* In Leads 1 and 3, in the tracings taken before and during the operation, the P waves are

FIGURE 2.

1), during the operation (Figs. 1 and 2, B-M) and post-operatively (Fig. 3). The findings are discussed below.

#### ELECTROCARDIOGRAPHIC FINDINGS

*Rhythm.* The basic rhythm preoperatively and during the operation, as well as during the subsequent twenty-four hours, was a sinus tachycardia, with premature ventricular contractions and a ventricular rate of 120. After twenty-four hours, normal sinus rhythm ensued, with a rate varying between 80 and 100. Ventricular premature contractions were noted preoperatively and during the course of the operation. In Lead 1 of Tracing A, taken preoperatively, coupled rhythm is seen, each normal complex being followed by a ventricular premature contraction each of which shows a slightly different configuration suggesting a varying origin. In Lead 1 of Tracing D, the ventricular premature contraction has its main de-

*Q wave.* Tracing A reveals a deep Q wave in Lead 1. Beginning with a depth of 3 mm., it reaches a depth of 6 mm. in Tracing F, at the time of entering and aspirating the pericardial sac. The Q wave then recedes to a depth of 2 mm. when the chest cavity was finally closed (Tracings L and M). Subsequently, it remained between 1 and 2 mm., but was no longer 25 per cent or more of the main deflection. No other leads at any time showed an initial downward deflection.

*Electrical axis.* At the time of operation, when the deep Q wave was present (Tracing F), a right ventricular preponderance is noted. Subsequently, the deviation of the electrical axis became normal.

*P wave.* In Leads 1 and 3, in the tracings taken before and during the operation, the P waves are

20 to 30 mm in height, becoming 10 to 15 mm in height during recovery.

**PR interval** The PR interval was 0.12 second throughout the period of observation.

**QRS interval** The QRS interval in the normal complexes was 0.06 second throughout the entire period of observation.

**ST segment** ST<sub>1</sub> is elevated in the tracings taken at the beginning of the observation, and

**Lead 4** Preoperatively (no tracing shown), P<sub>4</sub> was inverted, S<sub>1</sub> prominent, and ST<sub>1</sub> depressed. Subsequently the P waves and ST segments became practically isoelectric, and T<sub>4</sub> small and inverted.

#### SUMMARY

A bullet wound of the heart involving a branch of the left circumflex artery supplying the anterior and lateral portions of the left ventricle was noted

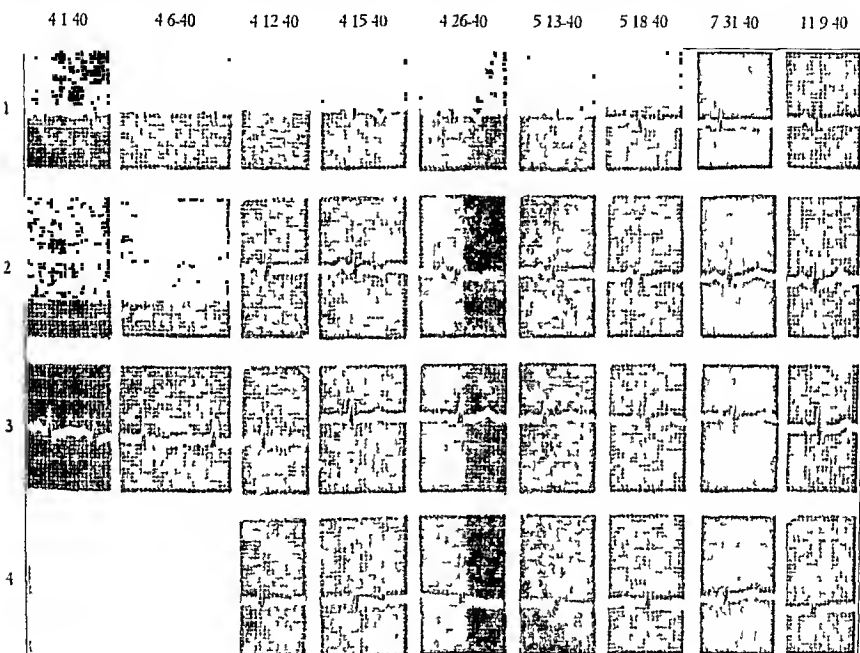

FIGURE 3

remains so in those taken during and one day after operation. Five days later, it became isoelectric and remained so thereafter. ST<sub>2</sub> was depressed before and during operation (10 to 20 mm). Postoperatively, it gradually reached a level about 0.5 mm below the isoelectric line. ST<sub>3</sub> changes were parallel with those of ST<sub>2</sub>.

**T wave** T<sub>1</sub> was inverted and became most apparent as the ST segment gradually became isoelectric. T<sub>2</sub> was upright, except for a period of about one month beginning twelve days postoperatively, when it was inverted. T<sub>3</sub> remained essentially upright throughout, although the depressed ST<sub>3</sub> segment at times obscured the interpretation

to be associated with the following electrocardiographic findings. Ventricular premature contractions arising in several foci were superimposed on normal sinus rhythm and sinus tachycardia. The premature contractions occurred both sporadically and at regular intervals, varying from coupling to tripling and quadrupling. The configuration of the premature contractions noted most frequently corresponded to that expected from the site of the injury. Q<sub>1</sub> became sufficiently deep at one period to cause deviation of the electrical axis to the right. No conduction defects were noted. ST changes corresponded to effects found in cases of coronary thrombosis with infarction.

T<sub>1</sub> became inverted—the most notable change.

It appears that in this case the preponderant effect on the electrocardiogram resulted from myocardial injury with necrosis, although definite pericardial disease was also known to be present.

## NEW HAMPSHIRE MEDICAL SOCIETY

### PROCEEDINGS OF THE ONE HUNDRED AND FIFTIETH ANNIVERSARY

House of Delegates, May 12, 13 and 14, 1941

(Concluded from the issue of July 24)

The work of the committee was approved by the Committee on Officers' Reports, and Dr. D. G. Smith urged that members attend the New England Postgraduate Assembly and take advantage of the Commonwealth Fund Fellowships; the report was adopted.

Dr. Charles H. Dolloff then read the report of the Committee on Mental and Social Hygiene.

#### *Report of the Committee on Mental and Social Hygiene*

The Committee on Mental and Social Hygiene has no special recommendations to make this year, and believes the Society should be given the opportunity to catch up on what has already been recommended in years past.

Demands are constantly being made for enlargement of the mental-hygiene program, with the establishment of more clinics in the larger centers, but the influence of the Society does not appear to be brought to bear on those who would be able to furnish the necessary money. The need of an extension of social service as part of the prophylactic program is obvious, but languishes for lack of support.

One of the outstanding contributions to the program of mental and social hygiene is the survey sponsored by Ex-Governor Huntley Spaulding.

Mental hygiene and social hygiene are primarily public matters, and must stand or fall according to the amount of public support they receive. It would be of great help if the force of this large body of physicians, through a legislative committee, could be put behind the legislation required for these public projects.

Right now our state institutions caring for the mentally afflicted are suffering from the dearth of good physicians and other employees, owing to their inability to pay adequate salaries and wages.

A medical and surgical building is being constructed

at the State Hospital, and the State School is about to open bids for the construction of another dormitory.

CHARLES H. DOLLOFF  
BENJAMIN W. BAKER  
JOHN B. McKENNA

Dr. D. G. Smith, of the Committee on Officers' Reports, recommended that the Committee on Public Relations be asked to watch for and to support bills in the legislature that provide for the improvement and extension of the mental-hygiene program and moved the adoption of the report; it was so voted.

The next report was that of the Committee on Tuberculosis.

#### *Report of Committee on Tuberculosis*

"A Good X-Ray Is Your Doctor's Best Aid in Discovering Early Tuberculosis" is the theme of the fourteenth annual nation-wide Early Diagnosis Campaign conducted in April each year by the tuberculosis associations throughout the nation.

For several years in this campaign the chest x-ray has been stressed as the correct diagnostic method for finding tuberculosis in its early, most curable stages. But this year, the x-ray looms as a great defense weapon, for it is the recognized means of ensuring that tuberculosis is kept out of the military forces of the country.

In World War I the main reliance was the usual diagnostic procedure—inspection, percussion and auscultation. Today it is known that this reliance resulted in rejection and discharge of but one eighth of the tuberculous subjects called into the service. Is it any wonder that the expenditures for hospitalization, compensation and rehabilitation for tuberculosis among the veterans is today entering the second billion of dollars by the federal government?

Today, through the program of chest x raying of national guard men and selective service men in New Hampshire, the federal government has been saved at least \$150,000 in eventual charges for tuberculosis.

Beginning with the induction of the 197th Regiment, Anti Aircraft, at Concord on September 16, 1940, and up to March 1 of this year, a total of 3167 national guardsmen and selective-service men have been chest x rayed at the Concord camp grounds, the state armories and the new induction center in Manchester. Of these men, 15 were rejected because of evidence of tuberculosis of the lungs, and several other men were deferred because of diseases of the chest revealed by x ray study.

It is difficult to total the costs of this service because of the fact that the staff members of official and nonofficial health agencies carried out the program in co-operation with the induction agencies, yet it is estimated that the cost did not exceed \$2500. This particular service is cited as an index of the tremendous value of the x ray in searching out the smallest evidences of the presence of tuberculosis of the lungs.

The tuberculin test is more and more demonstrating its value as an aid in the diagnosis of tuberculosis. With rapid reduction in the number of positive reactors to the test, its value as a screen in sifting out those harboring infection with tuberculosis bacilli becomes increasingly evident.

The value of tuberculin testing and chest x raying of positive reactors among contacts of tuberculous patients is well recognized.

More frequent use of the tuberculin test and chest x ray by physicians in their offices and in the hospitals can materially aid in early diagnosis.

New Hampshire continues to maintain an enviable position with reference to its tuberculosis death rate. The reduction in rate has been persistent and phenomenal, from 97.8 per 100,000 population in 1920 to 28.47 in 1939.

Many factors no doubt have and are contributing to the control and advance toward eradication of the disease in New Hampshire—better living and working conditions, the cure of many tuberculous patients through more prompt and better treatment, and the reduction in numbers of new cases developing through the destruction of tubercle bacilli at their source among the afflicted.

The sanatoriums at Glencliff and Pembroke report encouraging increases in numbers of patients receiving pneumothorax treatment. Technical improvement has given better results and fewer complications. Gratifying effects continue to be evident in patients receiving chest surgery. The generous and wholehearted cooperation of our chest surgeons and the hospitals has made possible arrest of the disease in certain patients for whom there could be but a future of chronic invalidism and ultimate disaster. This service has been performed at a minimal cost only through the generous spirit of cooperation already mentioned.

A difficult problem continues to exist in the necessity of providing for sanatorium treatment for tuberculous patients in accordance with present day standards of strict bedrest over long periods of time. The infirmary facilities at the Glencliff Sanatorium have been taxed to the utmost. Empty beds are present in the cottage wards but cannot be used except for convalescent patients, because of their inadequacy for hospital treatment and care.

The grateful appreciation of all concerned is extended to the practicing physicians of New Hampshire for their increasingly effective co-operation, particularly their willingness to urge and provide chest x ray films through the

hospitals at a nominal cost for clinic cases. The officers and directors of the New Hampshire Tuberculosis Association, the examining physicians at the chest diagnostic centers, the field nurses, the patients and the public join in this expression of appreciation. It is keenly realized that this generous sympathetic understanding and assistance on the part of our physicians is due to the keen desire of the members of the New Hampshire Medical Society to hasten the eradication of tuberculosis among the people, and to confidence in the services of the chest diagnostic clinics.

Your committee urges more use of the tuberculin test, either the Mantoux, using protein purified derivative, or the Vollmer patch test. We urge this for all contacts with tuberculosis, for all patients presenting suspicious symptoms or signs, in fact for all chronic coughers, losers of weight and tired people. We urge chest x ray for all positive reactors to the tuberculin tests.

Your committee is glad to be of assistance in the interpretation of chest x ray films sent to them by any member of the Society. This service is increasing, yet we urge more and more use of it.

ROBERT B KERR  
ROBERT M DEMING  
M DWYSON TYSON

On the recommendation of the Committee on Officers' Reports, the report was adopted.

Dr Parsons, chairman of the Committee on Memorials and Communications then presented four communications for consideration. The first was from the State Board of Health and concerned a proposed survey to determine the incidence of syphilis in low wage groups, to be undertaken with the co-operation of certain large industrial plants, some discussion followed, but no action was taken. The second was a resolution submitted by the New Hampshire Maternal Health Association, Incorporated, which read as follows:

WHEREAS, The American Medical Association at its Annual Convention in June, 1937, defined birth control as an integral part of preventive medicine and adopted a four point program to provide for scientifically tested methods of contraception and instruction in their use, the four points being to inform physicians clearly about their medical rights, to carry on research in materials and methods for the prevention of conception, to promote thorough instruction in contraception in medical schools, and to bring all dispensaries, clinics, and similar establishments under legal licensure and medical control, therefore, be it

RESOLVED, That the New Hampshire Medical Society endorses the stand taken by the American Medical Association and recognizes the need for medically supervised contraception as an integral part of preventive medicine.

The third was a communication from the American Medical Association concerning the hospital construction bill (No 1230) introduced into the United States Senate, the committee recommending that approval be extended, provided that construction be limited to that proved to be urgently

needed and that adequate maintenance be assured; this recommendation was adopted, as well as a supplementary one creating a special committee to act in an advisory capacity to the executive office of the State Board of Health on any contemplated hospital-construction project under this pending legislation.

It was voted to take off the table the motion in regard to the creation of a committee on public health; and it was then voted to create a new standing committee, the Committee on Public Health, consisting of three members. Subsequently, the tabled motion that the Committee on Public Health be instructed to consider the problem of the State Laboratory as a real competitor of the clinical pathologists was taken off the table and was approved. Furthermore, the accepted motion creating an advisory committee in regard to hospital construction was amended so that the matter was referred to the Committee on Public Health.

The final communication presented by the Committee on Memorials and Communications was a letter from the New Hampshire Farm Bureau Federation in regard to the formation of a co-operative to underwrite the costs of medical care to low-income groups in rural areas. Since accurate facts concerning the need for such a plan are lacking, the committee recommended that a special committee be appointed by the President to co-operate with representatives of the Farm Bureau in a thorough investigation of the problem. Dr. D. G. Smith, of the Committee on Officers' Reports, moved that part of the recommendation creating the appointment of a special committee be not accepted, that the rest of the recommendation be accepted and that the matter be referred to the Committee on Medical Economics, as had the question of enabling legislation covering medical-care insurance; it was so voted.

Dr. Benjamin P. Burpee then presented the report of the Committee on Infancy and Maternity.

### *Report of the Committee on Maternity and Infancy*

This is the seventh year during which the Committee on Maternity and Infancy of the New Hampshire Medical Society has conducted a study of maternal deaths, infant deaths and stillbirths that occurred during the preceding year. The study, as in the past, is an effort to analyze the causes of maternal deaths and to appraise, so far as possible, the problems relating to the causes of deaths among mothers and babies. All agree that, although the maternal death rates in New Hampshire and in the United States as a whole have shown an encouraging downward trend, there are still too many mothers

and too many infants under one year of age who die needlessly each year.

The committee has endeavored to collect as complete data as possible on each maternal death reported, and has analyzed the facts obtained with as impartial but scrutinizing care and judgment as is possible in cases where only abstract material is considered. No absolute or arbitrary conclusions can be drawn from such a study, but one can evaluate the cold facts in each case and suggest alternative procedures that might have aided in preventing the death. All this, of course, is done with the advantage of retrospect and without the element of the personal responsibility and emergency factors experienced by the physician in actual charge of the case.

The committee's remarks and conclusions must be understood at the outset to be entirely impersonal, since the name of the physician, the name of patient, the location of death and other identifying information are never known to the committee members. Only one person acting as agent must of necessity know these facts in order to collect the necessary data. That person is the director of the Maternal and Child Health Division of the State Board of Health. The study this year, as in the past, has been carried on with the co-operation of the Division of Maternal and Child Health of the State Board of Health.

Since the annual meeting of the Society last year the committee has held five meetings. These were as follows: November 20, 1940, and February 19, March 5, April 16 and April 28, 1941.

At each meeting the committee studied carefully the information collected on each case and considered every phase of the problem. Materials used in gathering data consisted of a copy of the death certificate, answers to questionnaires sent to the physician who signed the death certificate, and in most cases, facts gathered by personal interview of the agent with the physician and data from the hospital record. All cases were studied by number and all correspondence was transmitted through the Division of Maternal and Child Health.

After the cases were studied a letter was sent to the physician reporting the case, giving the committee's comments and whatever important suggestions the committee felt would be of interest or value. In some cases quite an interesting correspondence ensued between the physician and the committee, via the Division of Maternal and Child Health, in which frank comments were made from both sides. This seems to be a most wholesome practice, since out of such a medium of debate and study some excellent educational and helpful suggestions are bound to spring. The committee believes that much mutual benefit has been secured by this means.

Regarding the study of infant deaths under one year, the committee thought that the best that could be done was to reappraise these deaths as to causes reported. There were too many infant deaths reported to enable the committee to secure full data on all. Therefore, in the following pages a tabulation of causes will be set forth and some conclusions drawn.

Stillbirths were analyzed also from the standpoint of causes. Questionnaires were sent out to physicians reporting stillbirths, and excellent co-operation was obtained in the returns. A tabulation of chief causes will follow in the report.

### MATERNAL DEATHS

The committee has tabulated the maternal deaths for the calendar year ending December 31, 1940, according to the *International Classification for the Causes of Deaths*

(fifth revision) There were 24 maternal deaths reported, and all were studied. Following an appraisal of each case, the committee then reclassified the deaths into categories of causes according to the data received and conclusions drawn from that data, as follows

CODE NO	CAUSE OF DEATH	NO OF DEATHS
140	Abortion with mention of infection	3
142 (b)	Ectopic gestation (without mention of septic conditions)	1
146 (c)	Post partum hemorrhage	4
147 (b)	Puerperal septicemia (not specified as abort on)	1
147 (d)	Acute pulmonary embolism	3
148 (a)	Puerperal eclampsia	3
148 (b)	Mild toxemia of pregnancy	1
149 (b)	Other accidents of childbirth	3
	Cesarean section	1
	Myocardial infarction	1
	Heart failure	1
		24

After thorough study of each case, taking into consideration the events leading up to the death of the patient, the past history and the hospital record, the committee reclassified the cases as to causes of deaths, as follows

CAUSE OF DEATH	NO OF DEATHS
Toxemia of pregnancy (eclampsia and mild toxemias)	8
Cesarean section with complication (without consideration for indications)	1
Post partum hemorrhage	4
Puerperal sepsis	1
Causes not due to pregnancy	2
Cardiac failure	2
Accidents of pregnancy	3
Pelvic thrombosis with embolism	2
Ectopic pregnancy	1
Abortions	3
Unclassified	2
	24

Cases were further classified into three categories,—Group I, those in which the patient was at fault, owing to neglect, failure to seek medical advice prenatally and so forth, Group II, those in which the obstetric treatment was inadequate, Group III, those which were apparently unavoidable,—as follows

CLASSIFICATION	NO OF DEATHS
Group I	3
Group II	9
Group III	10
Unclassified	2
	24

In the unclassified group, one record was incomplete, and one death was not deemed to have been due to maternal causes

The causes of death in Group I, in which the patient was at fault, were as follows

CAUSE OF DEATH	NO OF CASES
Induced abortion	1
Toxemia of pregnancy (no prenatal care sought)	1
Hemorrhage (stony uterus—patient in extremis when seen)	1
	3

The causes of death in Group II, in which the obstetric care was inadequate, were as follows

CAUSE OF DEATH	NO OF CASES
Cesarean section	1
Criminal abortion	2
Eclampsia	3
Post partum hemorrhage	2
Pelvic thrombosis with pulmonary embolism	1
	9

The causes of death in Group III, in which the deaths were apparently unavoidable, were as follows

CAUSE OF DEATH	NO OF CASES
Intestinal obstruction	1
Eclampsia (cesarean done in 1 case)	4
Pelvic thrombosis	1
Pelvic abscess (furunculosis)	1
Ectopic pregnancy	1
Cardiac failure	2
	10

In comparison with the study of 1939 deaths, it is interesting to note that toxemia of pregnancy was still the chief cause of death. Only three fatal cesarean sections were performed, in contrast with five recorded for 1939. Two of these sections were deemed responsible for the patients' deaths, the other was done on a patient with marked toxemia, and the death was considered to have been due to the toxemia rather than to the operative procedure per se.

In the 1940 series, 23 cases were delivered in hospitals and 1 in the home. The following data on urban and rural residency are also of interest

COUNTY	URBAN CASES	RURAL CASES	TOTAL CASES
Bellamy	2	0	2
Carroll	0	1	1
Chester	0	1	1
Cook	1	0	1
Grafton	1	2	3
Hillsborough	8	2	10
Merrimack	1	0	1
Rockingham	3	0	3
Stratford	1	0	1
Sullivan	2	0	2
	19	5	24

No study is of value unless it is compared with findings of previous years. There were a few noticeable improvements found this year over those of last, and some conditions remained about the same. It is worthy to note that the co-operation manifested by physicians in reporting findings, giving data and answering questionnaires was greatly improved. Of twenty four questionnaires sent out, all but one were returned, with excellent and complete data. When visited, the physicians showed a genuine interest in the study and were most anxious to discuss all features of the case.

As indicated above, only three cesarean sections were performed, as compared with five for the previous year. Five autopsies were performed in 1940, however, as compared with six the year before. Indications for post mortem examinations varied somewhat in the two years, since more cases were due to definite causes this year. The committee believes, however, that whenever there is a doubt of the cause of death, an autopsy should be secured, if possible.

Hospital records were more complete than in former years, and it was noted with gratification that more physicians made out their own records instead of depending on hospital nurses to do so.

There is still a great deal to be desired in reference to hospital staffs requiring consultations on all operative deliveries. There has been a noticeable improvement in hospital technique and equipment. In some hospitals, new nurseries have been installed, which are well equipped for the isolation of infants. Other hospitals have secured incubators, put on fire escapes, unproved plumbing facilities and sterilizing equipment and so forth. This forward movement on the whole is encouraging and is a trend that the committee believes is due to more efficient hospital administration and better co-operation with public health agencies.

The ever-discouraging feature of any study on maternal deaths is the fact that toxemias of pregnancy continue to lead the list of all causes listed. Particularly discouraging is the fact that even when a diagnosis of toxemia of pregnancy is obvious from the records, little seems to be known by most physicians as to the treatment. Either very inadequate and futile "stabs in the dark" are made in treatment, or else no treatment is given. Not one case of toxemia studied in 1940 could be deemed as having been treated adequately.

The committee realizes that the treatment of toxemias of pregnancy is a controversial subject. Nevertheless, this fact seems to be no excuse for lax treatment of the patient with toxemia. The committee believes that patients with mild toxemias are allowed to go too long without proper treatment. A persistent rise of blood pressure over what is known to be the patient's normal pressure before pregnancy should be considered evidence of toxemia, even in the absence of albumin in the urine. Because of the persistent problem arising out of uncertainties in the treatment of toxemias, the committee will include in its recommendations a simple outline for the treatment of toxemias (this was included in the 1938 report). Let it be understood that the committee does not set itself up as an infallible authority in this matter, but believes the suggestions may prove of value to some.

The committee has presented an analysis of maternal deaths as to causes and as to facts that might be of interest as contributing to the death of the patient. It may be well to include at this point a tabulation of maternal death rates for a series of past years in order to note the trend in maternal mortality statistics:

YEAR	NO OF DEATHS	MATERNAL MORTALITY RATE PER 1000 LIVE BIRTHS
1930		62
1932		54
1933		63
1934		54
1935	46	61
1936	37	46
1937	34	43
1938	24	38
1939	25	31
1940	24	28

It will be noted that, up to 1936, maternal death rates had no appreciable variation. From 1936 on, the rates show a steady downward trend. This is probably not statistically significant as yet, owing to the smallness of the series of years. However, since New Hampshire's birth rate has remained almost constant for many years, such a downward trend, if continuous, will no doubt prove significant. The committee would like to think that this downward trend is due to better obstetrics or at least to concerted efforts on the part of the medical profession to improve technics at the time of delivery and to better prenatal care. Time alone can tell, and efforts must forever be strengthened. As yet it is not wise or logical for the profession to take much credit regarding the lowered mortality rates in maternity.

INFANT MORTALITY

The study of causes for infant deaths under one year was conducted by the committee from data appearing on the death certificates only. The large number of infant deaths reported did not permit an exhaustive analysis. However, the committee has tabulated infant deaths by causes as they appeared on the death certificate. The ages at which the deaths occurred were separated into three periods

It is obvious again, as in former reports, that prematurity was by far the chief factor leading to the death of the newborn. There was an improvement in the reporting of causes of deaths this year over that of 1939, fewer vague and meaningless diagnoses being recorded. Twenty-one autopsies were performed. This is a distinct improvement over last year. Following is a tabulation of causes of death in infants under one year of age divided into periods as to when the deaths occurred:

CAUSE OF DEATH	NO. OF DEATHS
Deaths occurring during the first day of life	
Prematurity	75
Congenital malformations	14
Cerebral hemorrhage	7
Birth injury	7
Asphyxia	2
Syphilis	1
Atelectasis	4
	110
Deaths occurring in the first month, exclusive of the first day	
Prematurity	21
Congenital malformations	10
Intracranial hemorrhage	7
Birth injury	5
Pneumonia	4
Gastroenteritis	3
Hemorrhagic disease of newborn	3
Whooping cough	2
Enlarged thyroid	1
Unknown	1
	57
Deaths occurring from the second to the twelfth month, inclusive	
Bronchopneumonia	49
Suffocation	9
Congenital heart	7
Meningitis	7
Gastroenteritis	6
Congenital malformations	6
Malnutrition	5
Prematurity	5
Unknown	5
Accidents	4
Congenital syphilis	1
Intussusception	1
Blood dyscrasias	2
	107

The total number of infants who died in 1940 under one year of age is 274; this is 33 less than that for 1939, when 307 infants died.

The total deaths from prematurity for 1940 numbered 101. It will be seen from the table that 75 of these infants died during the first day of life. Since such an astounding number of infants are lost owing to prematurity, it may be well to outline briefly a few important considerations in the care of the prematurely born infant. The committee believes that prematurity as a cause of death is, in many cases, preventable. The mere fact that an infant is born with a birth weight of 5½ pounds or less seems little excuse for the infant's death, provided, of course, that the infant has sustained no cerebral injury, has attained viability, and is in all other respects free from deformity or abnormality. The care of the premature infant involves, therefore, the following principles:

1. Extreme care should be exercised by the physician, nurses and attendants at the time of delivery to avoid trauma, unnecessary exposure or rough handling. "Jackknifing" as a method of resuscitation is condemned. Diagnosis before the onset of labor or during labor as to the possibilities of a premature infant should be attempted, and proper planning for the delivery should be considered. Teamwork practiced by the doctor, mother and nurse is essential to afford the best outcome. Equipment for resuscitation of the infant should be available at the time of de-

livery, and means for maintaining normal body temperature should be at hand. Time is a most important factor in the care of the newborn premature infant. Most of them die during the first few hours after birth and during the first day. After the first day, the infant has an increasingly good chance for life.

2 During labor, barbiturates should be cut down to a minimum. Premature infants do not tolerate sedation, particularly by barbiturates, and many infants born prematurely cannot be resuscitated under conditions in which the mother was given the usual dosage of barbiturates.

3 The maintenance of as nearly normal body temperature as possible is essential. Avoidance of excessive temperature should also be considered. An improvised heated crib built of simple materials and designed to keep fairly constant temperature is satisfactory. Heat can be provided by the use of hot water bottles or by a protected electric light bulb. A thermometer should be available to check the temperature of the crib at frequent intervals. (Plans for such a heated crib can be obtained from the committee or from the Division of Maternal and Child Health of the State Board of Health on request.)

4 Careful and scrupulous attention should be paid to avoidance of infections, particularly upper respiratory infections. Attendants should wear masks at all times.

5 Extreme care should be taken to provide adequate and proper nursing care and supervision of the premature infant. The physician should supervise all phases of the care, including feeding, handling and any special treatment. Transfusions are at times necessary. Handling of the infant should be reduced to an absolute minimum, and avoidance of drafts, changes of temperature and so forth should be considered.

6 Recent and studied observations have shown the definite value of the use of vitamin K at the onset of labor. It is a well known fact that the prothrombin concentration of any newborn's blood drops markedly almost immediately after birth. This is, in some cases, responsible for cerebral hemorrhage or bleeding. This fact is particularly of significance in the premature infant, whose blood prothrombin level and all blood mechanisms are relatively unstable. It is therefore recommended that synthetic vitamin K be given as a routine procedure during labor. Best results are obtained by giving vitamin K within two hours before birth. However, no matter when given during the latter part of labor, definite results are obtained. The dosage is recognized to be 32 mg given intramuscularly. If synthetic vitamin K has not been given to the mother during labor, then it should be administered to the infant immediately after birth. The dosage is also 32 mg, given intramuscularly.

The committee recognizes the multiplicity of problems arising in the care of the premature infant and cannot attempt to answer all of them. The foregoing is included for what value it may prove in the handling of some future case. Two facts are certain in considering care of the premature infant: first, that special care and attention must be provided and, secondly, that time cannot be wasted in applying the best and most recognized treatment procedures.

The infant mortality rates per 1000 live births by years are as follows:

YEAR	RATE
1935	54
1936	4
1937	48
1938	48
1939	45
1940	32

#### STILLBIRTHS

One hundred and eighty-seven stillbirths were reported in 1940, a figure that compares with 211 in 1939. Questionnaires were sent to all physicians reporting still births, and answers were received for 149 cases.

The causes of stillbirths were tabulated as follows:

CAUSE	NO OF CASES
Prematurity	29
Congenital deformity	27
Cause unknown	24
Instrumental delivery	17
Other causes (var ed)	17
Toxemia of pregnancy	16
Hemorrhage (placenta previa or premature separation)	11
Prolapsed cord	4
Syphilis	3
Cerebral hemorrhage	1
	<hr/> 149

Twenty-nine infants were stillborn owing to prematurity, and 27 had some congenital malformation; in 1939, the corresponding figures were 46 and 15. The latter cause is of course unpredictable and unpreventable, whereas premature deliveries might be preventable in the light of recent medical practices involving careful prenatal supervision.

If one studies the foregoing tables on causes of death in infants under one year of age and on stillbirths, the total number of infants lost because of premature births was 130.

There seems to be no conclusion that can be drawn from the number of stillbirths reported during the past few years as shown by the following table:

YEAR	NO OF CASES
1937	181
1938	143
1939	211
1940	187

#### COMMENTS AND RECOMMENDATIONS

As in the past the committee has prepared certain comments and recommendations based on the study carried out. Some definite problems have presented themselves as a result of this year's study. It will be noted that toxemias of pregnancy present a real problem, especially so far as treatment is concerned. Because of continued confusion as to the treatment of toxemia or lack of knowledge as to any type of treatment that might be tried, the committee is including in this report a repetition of the recommendations made in the 1938 report concerning the treatment of toxemia. The committee realizes that no one treatment can be set up as infallible, nevertheless, a simple routine as follows may prove effective:

Absolute quiet.

Sedation (a barbiturate).

Concentrated magnesium sulfate and glucose intravenously (the dose should be regulated according to the needs of the individual case).

Rapid digitalization in all cases with convulsions or threatened with convulsions (for the average patient, a total dose of 20 to 25 gr within twenty-four hours).

The main principles of the treatment consist in sedation, dehydration and, when necessary, cardiac stimulation.

The committee wishes to refer to recommendations made in previous years, with particular reference to indications for cesarean section. A rather comprehensive outline of indications for sections was included in the 1940 report. Other recommendations were that laboratory facilities be used when available for aiding in the diagnosis of conditions that might lead to hazards during delivery; that the proper use of the x-ray in pelvimetry is of value when performed by a competent radiologist; that an *accouchement forcé* done for any condition whatever is condemned; that manual removal of a placenta is unjustifiable unless there is excessive and uncontrollable bleeding; and that more frequent consultations be demanded by hospital staffs for operative deliveries. Recommendations based on the study of 1940 maternal deaths are as follows:

1. Since there have been more deaths from abortions reported for the year 1940, the committee believes that every effort should be made on the part of physicians and authorities to apprehend the offenders and take steps to put a stop to such practices. This recommendation has reference to induced abortions performed without therapeutic indications.

2. The committee considers that too few post-mortem examinations are performed. Any death the cause of which is obscure should be studied in the light of post-mortem findings. It is the belief that most requests for autopsies will be granted if physicians make an effort to secure permissions. Post-mortem vaginal examinations can always be done and may reveal the cause of death.

3. The committee suggests that, in areas where such a procedure is possible, physicians who abhor doing obstetrics and who have no interest in its practice be urged to refer such cases to an obstetrician or to a physician whose chief interest is obstetrics.

4. More care should be exercised in making diagnoses of conditions arising in the prenatal and post-partum periods and of conditions occurring at the time of delivery. Diagnoses appearing on death certificates indicate, in some cases, the failure or lack of effort in coming to definite conclusions. Laboratory facilities, x-rays and careful examinations should be utilized in all cases.

5. Since the use of the sulfanilamide group of drugs has been increased, and since its successful use is dependent on proper dosage, the committee recommends that hospitals make the technics and the tests for blood concentration of these drugs available for physicians' use. To be effective the concentration of sulfanilamide in the blood should be brought up to 10 mg. per 100 cc. and maintained at that level. If the dose prescribed does not attain this end, it is in all probability not adequate. For sulfathiazole the blood concentration should be brought to 3.0 or 3.5 mg. per 100 cc. and maintained at that level.

6. The committee wishes to repeat that there is a tendency on the part of physicians to allow toxemias to continue too long without treatment. A persistent elevation of blood pressure over the known normal for the patient should be considered indicative of toxemia, even without the appearance of albumin in the urine. It is safer to consider that a patient has a mild toxemia until proved otherwise than to ignore it. Abnormal gains in weight should always be viewed with suspicion.

7. The committee recommends that patients be continually urged to seek prenatal supervision. Proper prenatal care should include visits of at least once monthly for the first seven months, and thereafter twice monthly. More frequent visits should be advised during the last trimester if indicated. Prenatal care should include a complete history and physical examination, including a Wassermann test at the outset and follow-up blood-pressure readings, urinalyses, hemoglobin determinations and blood examinations at monthly intervals. Careful records of weight should be kept.

8. Physicians should be discouraged in attempting to perform operative deliveries in the home.

9. Attempts to perform versions without deep anesthesia should be frowned on.

10. It is recommended that physicians keep practical records on all obstetric patients for whose care they are responsible.

11. The committee believes that the physician should make out the hospital record rather than to depend on nurses to do it for him.

12. Whether a delivery is in the hospital or home, the physician should not leave until he is certain the mother's condition and that of the baby are satisfactory.

13. The committee has observed that, in several cases reported this year, sudden deaths occurred on the first day the patients were allowed out of bed. In each case there had been a rise in temperature during the puerperium. It is believed that in cases in which the temperature becomes elevated the possibility of a pelvic thrombosis should be considered and that the patient should be kept in bed until the temperature has remained normal for at least three days. Emboli are common in cases of pelvic thrombosis.

Finally, the committee is most grateful for the excellent co-operation shown this year by physicians. The returns on questionnaires were especially helpful. The frank and complete comments made on many cases were most appreciated. Continued co-operation, interest and further suggestions for this study are earnestly solicited. The committee also expresses its thanks and appreciation to the hospitals that have helped make this study possible. To the Division of Maternal and Child Health of the State Board of Health, the committee expresses its appreciation for the facilities of the division and for the work performed in helping to prepare this report.

ROBERT O. BLOOD, *Chairman*  
BENJAMIN P. BURPEE  
MARION FAIRFIELD

After commending the committee for its excellent work, Dr. D. G. Smith, of the Committee on Officers' Reports, recommended the adoption of the report and the mailing of a copy to each hospital and physician in the State; it was so voted.

The report of the Committee on Child Health was then presented.

### *Report of the Committee on Child Health*

Your committee held five meetings during the year. There was considerable discussion at our meetings of the law making compulsory the reporting of children

with impaired hearing. The State Board of Health asked our advice regarding the formulation of rules and regulations for the proper execution of the law.

The committee has continued to follow as closely as possible progress in child health work, especially as exemplified by the American Academy of Pediatrics. We have continued in close co-operation with the Division of Maternal and Child Health.

At the suggestion of the committee, Dr. Franklin Rogers delivered a radio broadcast on the preschool child over Station WFEA. This has also appeared in *New Hampshire Health News*.

COLIN C STEWART  
TRAVIS P BURROUGHS  
FRANKLIN N ROGERS

The report was accepted.

Dr. Henry H. Amsden read the report of the neurologist.

### Report of the Neurologist

The following deaths have occurred since the last annual meeting.

NAME	ADDRESS	DATE DECEASED
Ballard, Clarence P	Penncook	March 4, 1941
Bartlett, Walter A	Manchester	August 12, 1940
Beaton, Alexander A	Franklin	August 22, 1940
Burt, Edward D	Lincoln	December 2, 1940
Clow, Fred E	Wolfeboro	January 4, 1941
Gilman, Louis L	Rochester	April 11, 1940
Goldsmith, Chester L	Winchester	July 26, 1940
Hubbard, Osmon H	Keene	January 5, 1941
Huse, Ernest L	Meriden	December 21, 1940
Mackenzie, Nicholas Y B	Andover	November 27, 1940
Marks, Homer H	Berlin	April 11, 1941
Morrill, Sibley G	Concord	December 28, 1940
Pherson, Frank J	Manchester	August 27, 1940
Sheldon, Harold L	Troy	September 24, 1940

HENRY H AMSDEN

As matters of new business, Drs. Joseph J. Cobb, of Berlin, Alfred Daudelin, of Nashua, Frank S. Lovering, of Moultonborough, Allen P. Richmond, formerly of Dover, and Lewis G. Hildreth, of Marlboro, were made affiliate members of the Society.

Dr. Wilkins spoke in favor of a change in the by laws whereby one dollar from the dues of each member would be contributed to the Benevolence Fund, rather than fifty cents; he made a motion to this effect, which was seconded and laid over until the following day.

Dr. D. G. Smith moved that the Advisory Committee on Medical Relief be discharged and that its duty be transferred to the Committee on Medical Economics; it was so voted. He then read a letter from the Commissioner of Public Welfare requesting the approval of Dr. L. Theodore Togus's acceptance of his appointment as a member of the

Medical Advisory Committee on Eye Conditions; he moved approval, and it was so voted.

The first meeting of the House of Delegates was adjourned at 11:00 p. m.

\* \* \*

The House of Delegates convened at the Hotel Carpenter, Manchester, on May 13, 1941, at 8:30 a. m., with Vice Speaker Timothy F. Rock, of Nashua, presiding.

The following members answered the roll call.

The President, *ex officio*  
The Secretary-Treasurer, *ex officio*  
Norris H. Robertson, Keene  
Leslie K. Scammon, Hanover  
Frederic P. Lord, Hanover (alternate for Willard A. Bates, Littleton)  
Deering G. Smith, Nashua  
Henry O. Smith, Hudson (alternate for Charles H. Cutler, Peterboro)  
Clarence E. Dunbar, Manchester  
George V. Fiske, Manchester  
George C. Wilkins, Manchester (alternate for Luther A. March, Nashua)  
Charles H. Parsons, Concord  
Herbert B. Messinger, Franklin (alternate for Robert J. Graves, Concord)  
Martha I. Boger-Shattuck, Portsmouth  
Frederick S. Gray, Portsmouth  
Anthony Peters, Portsmouth (alternate for James S. Sanders, Rye)  
Edna Walch, Dover  
Henry C. Sanders, Jr., Claremont

Dr. D. G. Smith, for the Committee on Officers' Reports, moved the acceptance of the first set of changes in the by laws proposed on the previous day and the abolishment of the Committee on Maternity and Infancy, after some discussion it was so voted. He then moved the adoption of the change raising the annual contribution to the Benevolence Fund from the dues of each member from fifty cents to one dollar; it was so voted.

A letter relative to the need of more medical officers for the Reserve Corps and for active duty was discussed.

The second meeting of the House of Delegates was adjourned at 9:15 a. m.

\* \* \*

The House of Delegates convened at the Hotel Carpenter, Manchester, on May 14, 1941, at 8:30 a. m., Vice Speaker Rock presiding.

The following members answered the roll call.

The President, *ex officio*  
The Secretary-Treasurer, *ex officio*  
Clarence O. Coburn, Manchester (alternate for Richard W. Robinson, Laconia)  
Francis J. C. Dube, Center Ossipee  
Frederic P. Lord, Hanover (alternate for Willard A. Bates, Littleton)  
Deering G. Smith, Nashua  
Henry O. Smith, Hudson (alternate for Charles H. Cutler, Peterboro)

Clarence E. Dunbar, Manchester  
 George V. Fiske, Manchester  
 George C. Wilkins, Manchester (alternate for Luther A. March, Nashua)  
 Frederick S. Gray, Portsmouth  
 Anthony Peters, Portsmouth (alternate for James Sanders, Rye)  
 Edna Walck, Dover  
 Albert E. Barcomb, Rochester

Dr. Lord reported for the Committee on Nominations as follows:

#### OFFICERS

*President:* Charles H. Dolloff.  
*Vice-President:* Henry C. Sanders, Jr.  
*Secretary-Treasurer:* Carleton R. Metcalf.  
*Councilors* (five-year term): Cleon W. Colby, John A. Hunter.  
*Trustee* (three-year term): Samuel T. Ladd.  
*House of Delegates:* speaker, Timothy F. Rock; vice-speaker, Charles H. Parsons.  
*Delegate* (American Medical Association): Deering G. Smith.  
*Alternate Delegate* (American Medical Association): Emery M. Fitch.  
*Necrologist:* Henry H. Amsden.

#### STANDING COMMITTEES

*Amendments to Constitution and By-Laws:* James B. Woodman, Frederick S. Gray, W. J. Paul Dye.  
*Child Health:* Colin C. Stewart, Jr., Travis P. Burroughs, Franklin N. Rogers.  
*Control of Cancer:* George C. Wilkins, Howard N. Kingsford, George F. Dwinell.  
*Maternity and Infancy:* Robert O. Blood, Benjamin P. Burpee, Marion Fairfield.  
*Medical Economics* (three-year term): Richard W. Robinson.  
*Medical Education and Hospitals:* John P. Bowler, James W. Jameson, Herbert L. Taylor.  
*Mental and Social Hygiene:* Charles H. Dolloff, Benjamin W. Baker, John B. McKenna.  
*Public Health:* Chester L. Smart, Harris E. Powers, Anthony E. Peters.  
*Public Relations:* Charles H. Dolloff, Henry C. Sanders, Jr., Carleton R. Metcalf, Robert J. Graves, Joseph N. Friborg.  
*Publication:* Carleton R. Metcalf, Warren H. Butterfield, Ellsworth M. Tracy.  
*Scientific Work:* Carleton R. Metcalf, Frederick P. Scribner, Nathan T. Milliken.  
*Tuberculosis:* Robert B. Kerr, Robert M. Deming, M. Dawson Tyson.

The report was accepted. The Secretary was instructed to cast one vote for Dr. Dolloff as president; this was done, and he was declared duly elected.

Dr. J. J. Morin, of Rochester, and Dr. H. L. Taylor, of Portsmouth, were nominated for the office of vice-president, in addition to Dr. H. C. Sanders, Jr. Following written ballots, it was announced that Dr. Sanders had received 13 votes, and Dr. Morin, 1; Dr. Sanders was declared duly elected.

The Secretary was instructed to cast one ballot for Dr. Metcalf as secretary-treasurer, and one for the remainder of the officers and committee members as nominated; this was done, and all were declared duly elected.

Dr. Coburn moved that the Society, through the House of Delegates, extend a vote of thanks to Dr. H. O. Smith for his work in bringing the history of the New Hampshire Medical Society to date and compliment him on his efforts as chairman of the committee in charge of the one hundred and fiftieth anniversary; it was so voted. He then moved that a vote of appreciation and thanks be extended to the committee that had had charge of arranging the very interesting and popular medical exhibit; it was so voted.

Dr. Metcalf moved that a vote of gratitude be extended to the members in Manchester who had arranged the details of the meeting; it was so voted.

Dr. Wilkins raised the question whether certain moneys from the General Fund should be transferred to the Benevolence Fund, thus providing a small income that could be used for needy cases. After some discussion, it was voted that the trustees be given power to expend money from the General Fund for the relief of needy members.

After some discussion, it was the consensus that a social gathering similar to the one held on the previous evening be held for the next two or three years.

It was further decided that the 1942 meeting be held in Manchester.

Dr. Wilkins moved that a vote of thanks be extended to Dr. George Dwinell for his work in scheduling and arranging the commercial exhibits during the previous six or seven years; it was so voted.

Dr. H. O. Smith called attention to the fact that the badge being used by the members of the Society was a replica of one presented to the members in 1906 by the president, Dr. F. A. Stillings;

at that time it was voted that the button be made a permanent badge, but the vote was forgotten three years later. He also said that at one time the Society had had a valuable reference library, its nucleus being the gifts of Dr Joshua Brackett and his widow. In 1891, there were over three

hundred volumes at Dr Irving A. Watson's office at the State House, however, no trace of these books can be found.

The third and final meeting of the House of Delegates was adjourned at 9:25 a.m.

CARLETON R. METCALF, *Secretary*

## MEDICAL PROGRESS

### THE TREATMENT OF DEHYDRATION IN PATIENTS WITH HYPERTROPHY OF THE PROSTATE, RETENTION OF URINE AND IMPAIRMENT OF RENAL FUNCTION\*

F. A. SIMEONE, M.D.

BOSTON

OF recent years, the problem presented by hypertrophy of the prostate and the interference with the normal function of the urinary organs caused thereby has been discussed in the literature largely by articles dealing with the technic of prostatectomy, whether by the transurethral, transvesical or perineal routes, and with analyses of end results of such operations. Discussions of measures to improve the badly disorganized general condition shown by many such patients, so that they may survive any form of operation have been less numerous. It is nevertheless essential to point out that the gratifying reduction of both mortality and morbidity of earlier years was the result of improvements in the preoperative and postoperative conduct of the patients rather than of improvements in operative technic, however valuable these may have been. The removal of the prostate in two stages resulted from a realization of the necessity for restoring the patient's disordered metabolic and chemical processes to a condition as nearly normal as possible before subjecting him to prostatectomy. Thus, in 1914, Pilcher<sup>1</sup> stated:

The chief indication is primarily to relieve the retention of urine rather than the removal of the prostate. If we could dissuade surgeons, as a rule, from the course of immediately taking out a prostate which is known to be obstructive, we would do much to help the cause of the prostatites.

The cardiovascular and the renal excretory systems bear the brunt of the secondary effects of prostatic hypertrophy. In patients of the age group in which hypertrophy of the prostate occurs, the heart and circulation are often already the seat of natural changes that decrease, some times practically to annihilation, the reserve that these systems possess in men of younger age groups. When obstruction to the outflow of urine from the kidneys occurs, the burden of an increased arterial blood pressure is added to the already overtaxed heart. When such elevation of blood pressure has existed for a long time, a rapid fall of blood pressure following decompression of the urinary passages, such as that afforded by catheterization, may induce profound changes in the blood flow through vital organs. Certain cases of disorientation, coronary occlusion and oliguria or anuria after too rapid decompression of the obstructed bladder may be referable to such circulatory changes. The treatment of the failing heart and circulation thus assumes a major role in the management of patients with prostatic hypertrophy of long standing.

The secondary effects of the obstructing prostate on the renal excretory system itself are referable principally to infection and to derangement of renal function. The burden that infection places on the bodily economy needs no emphasis. The service that chemotherapy, particularly the use of sulfanilamide and sulfathiazole,<sup>2,3</sup> has rendered to those suffering from infection in the urinary tract is now generally recognized. The fact that these drugs act in especially small

\*All articles in this series will be published in book form the current volume is *Medical Progress Annual 1940* (Springfield Ill no. 8 Charles C. Thomas Company 1941 \$4.00).

<sup>1</sup>From the Urology, and Clinic, Peter Bent Brigham Hospital.  
<sup>2</sup>Instructor in general urinary surgery Harvard Medical School fellow urology Peter Bent Brigham Hospital.

amounts in urinary infection is particularly fortunate. To be sure, they are not curative in the presence of obstructing lesions of the urinary tract, but this does not detract from their value as adjuncts to bladder drainage in preparing patients with urinary retention and infection for prostatectomy.

Among the widespread effects of renal insufficiency accompanying prolonged urinary obstruction, the most serious from the point of view of the urologic surgeon is the derangement in water balance and in the electrolyte pattern of the body fluids. Clinically, interest centers on the treatment of the dehydration that almost invariably attends the deranged electrolyte composition of the body fluids. The importance of water and electrolytes for the proper execution of body functions cannot be overemphasized. The maintenance of normal metabolic reactions, as well as such complex functions as wound healing, depends on a proper complement of water and electrolytes. A brief summary of the problems encountered in the management of water balance or dehydration in urologic patients is therefore profitable.

The proper management of dehydration depends on three premises: recognition of the state of dehydration, detection of the underlying causes and familiarity with methods available for correcting the condition.

#### THE DIAGNOSIS OF DEHYDRATION

The clinical signs of dehydration are easy to recognize. The skin is warm, dry, wrinkled and inelastic. The eyeballs are soft. The tongue is dry and difficult of motor control so that speech is thick. If dehydration is sufficiently severe, acetone may be detected on the breath. The sensorium is dulled in varying degrees up to coma. The pulse is rapid, but the arterial blood pressure may be normal until the condition is far advanced, when a state resembling secondary shock supervenes. Acidosis is usually present, with its attendant respiratory changes, but there may rarely be alkalosis, even when ketone bodies are being excreted in the urine.

Such clinical signs as have been described, however, usually accompany a loss of 6 per cent or more of the body weight in water. Slight degrees of dehydration are often difficult to recognize. To detect dehydration before too serious metabolic disturbances have been created, several laboratory tests have been employed. The commoner ones are the following.

*Red-cell count and hematocrit determination.* An increase in the number of red cells in the blood stream, as determined by red-cell counts and hematocrit determinations, has been interpreted as indicating a decreased content of water in the blood (anhydremia) and, indirectly, a decrease in the volume of interstitial fluid (dehydration). Such an interpretation is justified in the absence of primary or secondary polycythemia from other causes, such as cardiopulmonary disease. The findings, however, are not always dependable. The tests may be normal when the dehydration is slight, because of the efficiency of the homeostatic mechanisms in maintaining constancy in the blood by drawing on the fluid stores in the interstitial (subcutaneous) tissues. When dehydration has been severe and of long standing, anemia develops secondary to destruction, as well as to depressed formation, of red blood cells. A normal or subnormal red-cell count and hematocrit determination may thus be misleading.

*Specific gravity of the blood and serum-protein concentration.* These tests are as easily done as the red-cell count and the hematocrit determination.<sup>4, 5</sup> They are subject to the same faults, however. Considerable interstitial fluid may be lost before any marked change becomes apparent in the concentration of the serum or plasma protein. On the other hand, one may encounter normal plasma-protein concentrations or actual hypoproteinemia in severe chronic dehydration because of the destruction of blood proteins when anhydremia is prolonged.

*Study of the electrolyte pattern of the blood plasma.* Here again the numerous reactions that maintain stability within the circulating fluids militate against early detection of dehydration until the condition has advanced so far that the homeostatic mechanisms begin to fail. At this point, one almost always finds a depression in the total-base component of the blood plasma, represented largely by sodium. The base depletion, by conditioning an equivalent loss of water, may be a primary cause for the dehydration (as in patients with biliary, pancreatic and intestinal fistulas), or it may be a secondary effect of prolonged or severe dehydration that has caused an impairment of renal function. In fact, so long as there is normal renal function,—or perhaps more accurately, so long as there is opportunity for normal renal function,—the total base of the blood plasma remains normal, even in the presence of moderately severe dehydration.

The value of estimating the electrolyte pattern of the blood lies in the information derived therefrom concerning the *degree* of derangement present and the approach suggested thereby for fluid replacement therapy.

*Estimation of the fluid need of interstitial tissue.* Hopps and Christopher<sup>6</sup> adapted the intradermal wheal absorption test of Aldrich and McClure to the study of dehydration in surgical patients. The test consists in the intradermal injection of 0.2 cc. of physiologic saline solution to raise a wheal, whose rate of disappearance is then measured. Normally, such a wheal disappears in fifty five or more minutes. A decreased disappearance time indicates a scarcity of subcutaneous fluid, or dehydration. Actually, however, the test probably reflects the existing osmotic conditions in the skin and subcutaneous tissues and not necessarily the lack of body water. Thus Kunde<sup>7</sup> found that the disappearance time decreased in cases of hydropigenous nephritis. In fact, it was possible to detect a decrease in the disappearance time even before the appearance of edema. Cases exhibiting edema, however, may still present the picture of dehydration in the broad sense of the term. Cases in which the total content of body water is normal or actually greater than normal might more properly be considered to represent disordered distribution of body water rather than dehydration.

It becomes apparent that slight changes in the concentration of plasma constituents, which may be sufficient to call into action the numerous regulatory mechanisms that preserve constancy while dehydration is progressing, cannot be detected by the usual analytical methods. Determinations of blood volume are not applicable to the study and treatment of early clinical dehydration. Evaluation of the Aldrich-McClure intradermal wheal absorption test must wait until more experience has been had with the test. The activity of the salivary glands, however, is a sensitive indicator of the state of hydration of the body. Long before ionic changes are demonstrable in the blood, the withdrawal of interstitial fluid causes a diminution in the blood flow through the salivary glands, the secretions from which are thereupon impoverished. Thus, the best index of early dehydration is the old clinical observation of dryness of the buccal and oral mucous membranes. Dysphagia is frequently present and may appear early in patients suffering from prostatism. Since dehydration may actually be secondary to hyposthenuria, the excretion of normal, or greater than nor-

mal, volumes of dilute urine is not inconsistent with dehydration.

The value of blood chemical determinations is not to be belittled, however. They at least demonstrate the degree of dehydration, and the nature of the shift in electrolyte pattern serves as a guide for replacement therapy.

#### ETIOLOGIC FACTORS IN DEHYDRATION

For convenience of description, the causes of dehydration fall into two major groups: those in which deficiency of fluid in the body results either from lack of fluid intake or from loss of water and salts through wastage of body secretions, and those in which water is lost secondarily because of disturbances in the electrolyte composition of body fluids due to abnormal function of the kidneys. Dehydration secondary to hemorrhage or loss of plasma through denuded skin surfaces, as in severe burns, is a special case that belongs to the first category. The treatment of the dehydration encountered in the first group has been discussed in several publications (Maes and Davis<sup>8</sup>). The second group of cases, which are of special interest to the urologist, however, have received little attention. The frequency with which patients with urinary retention and impaired renal function exhibit a dehydration that is practically always secondary to a multiplicity of factors warrants further analysis of the nature of dehydration in patients with hypertrophy of the prostate, urinary retention and renal insufficiency.

The principal factors determining dehydration in such urologic patients are insufficient fluid intake, loss of water and salts from the body and electrolyte imbalance due to impairment of renal function, with consequent loss of body water.

*Insufficient fluid intake.* Metabolic activity involves a daily inevitable loss of water from the body. The greatest volume is lost by vaporization from the skin and lungs. The actual amount lost naturally varies with body temperature, muscular activity and the temperature and humidity of the environment. On the average, however, 2000 cc. a day are lost by vaporization. Next in amount is the water lost through the kidneys in the form of urine. So long as renal function is normal, the water excreted by this route varies inversely with the amount of water lost through other channels. When the water stores in the body are low, the normal kidney conserves water by excreting a concentrated urine. The diseased kidney, however, is unable to extract water efficiently from the glomerular filtrate, and water is wasted. Thus, the normal kidney can excrete an average of 35 gm

of solids in little more than 400 cc. of urine. The diseased kidney, which is unable to concentrate beyond a specific gravity of 1.010, requires 1500 cc. to excrete the same amount of solids. Normally, the water lost in the stools is negligible.

For metabolism to proceed normally, this inevitable daily loss of body water, amounting to about 3500 cc., must be replaced, and this is accomplished by the ingestion of water with food or drink regulated by the sensation of thirst. The metabolic water derived from the breakdown and transformation of food elements seldom amounts to more than 500 cc., and in patients who have limited their food intake because of illness, water derived from this source is negligible. It is noteworthy that patients with urinary retention, renal insufficiency and nitrogen retention often are not thirsty, even though they present obvious clinical signs of dehydration. They sometimes actually complain that water "tastes bad" and refuse to drink. A vicious circle is thus established whereby dehydration, which may have begun by electrolyte derangement, is aggravated by inadequate fluid intake.

*Loss of body fluid through abnormal channels.* In addition to loss of water in the urine and by vaporization, which, except in degree, does not differ from the normal, fluid may be lost by various abnormal means. These are common knowledge, and the problems presented by such avenues of fluid loss as biliary and intestinal fistulas are not germane to the consideration of dehydration in the prostatic patient with renal insufficiency and nitrogen retention. The urologist is often confronted, however, with the necessity of replacing fluid lost by vomiting and sometimes by diarrhea. It should be pointed out here that vomiting in such patients is not prone to cause alkalosis but rather dehydration and acidosis because of the relative achlorhydria in azotemia. What chloride escapes in the vomitus does so in company with sodium.

*Loss of body fluid because of changes in the electrolyte pattern of the blood secondary to impairment of renal function.* Changes in the electrolyte composition of the blood associated with impaired renal function are varied. Irrespective of the type of renal disease, however, the principal changes are referable to the total base (principally sodium) and the chloride and bicarbonate acid ions.

The determination of the total-base equivalence of blood plasma offers an accurate index of its osmotic characteristics, which depend in large measure on the electrolyte content of the plasma. The total-base concentration in the plasma of patients

with renal insufficiency is almost invariably low. The mechanism whereby salt is spared by the kidney is lost. Water is lost along with the base, and dehydration ensues. It is only with far advanced total-base depletion and disordered renal function that water is retained in spite of low total-base concentration in the blood and tissue fluids.

The mechanism for base depletion in renal disease is not entirely clear, but an important role is no doubt played by the inability of the diseased kidney to synthesize ammonia, with which to excrete nonvolatile acids as ammonium salts. Instead, they are excreted as salts of fixed base derived from the blood plasma.

In renal disease, the concentration of the chloride ion in the blood is very variable. Thus in 148 cases of varied etiology, Peters, Wakeman, Eisenman and Lee<sup>9</sup> found that the chloride determinations were below normal limits in 56, and above in 44. A low blood-chloride concentration, however, does indicate almost invariably a low total-base or total-electrolyte concentration in the blood, with consequent loss of water in the attempt of adjustive mechanisms to restore osmotic equilibrium. A low total base, however, does not necessarily imply a low chloride concentration. The usually reciprocal relation between the concentrations of the chloride and bicarbonate ions prevents the loss of chloride when the total base concentration has become low, that is, the bicarbonate ion variation is the principal mechanism whereby a balance is maintained between the acid and base equivalence of the blood electrolytes. Hence, acidosis usually accompanies dehydration, and base is lost from the blood without a corresponding loss of chloride.

Even in dehydration secondary to electrolyte imbalance, the very causation of the dehydration makes impossible its early detection by chemical study of the blood plasma. Changes in the electrolyte pattern of the blood are detectable by gross methods only when the causative factors have progressed to such degree that compensation for them by the usual homeostatic mechanisms has begun to fail.

#### TREATMENT OF DEHYDRATION

In the management of the postoperative patient with urinary retention and impairment of renal function, the administration of 3500 cc. of fluid every twenty-four hours is sufficient to replace the inevitable fluid loss from the body during convalescence. It ensures the availability of about 1500 cc. of water for excretion in the urine, and this is sufficient for the excretion of 35 gm. of solids even by kidneys that cannot concentrate beyond

a specific gravity of 1.010. Fluid lost through vomitus or other abnormal channels must be measured and replaced in the form of physiologic saline and dextrose solution, in addition to the 3500 cc. When the function of the kidneys is normal, it makes little difference in what form the inevitable fluid loss from the body is replaced, provided that 8 to 10 gm. of salt per day is furnished. Fluid lost through acute hemorrhage is, of course, best replaced by whole blood, and the protein-rich fluid lost in exudates, by blood plasma or serum.

The treatment of dehydration in the presence of primary or secondary electrolyte imbalance requires special consideration. The choice of the various types of fluids available for parenteral therapy depends on the nature and degree of the electrolyte imbalance, and the success of therapy depends in part on the choice of proper fluids and in part on the degree to which renal function can be restored. It is essential to remember that each case of dehydration with disturbed blood-electrolyte composition presents problems peculiar to itself, and that treatment must therefore be individualized. Nevertheless, certain general principles may be formulated.

*Cases in which dehydration is mild and renal function is normal.* These cases are seldom of any concern. The dehydration is usually secondary to insufficient fluid intake because of the associated illness. Fluid loss through abnormal channels plays only a small part, if any. Therapy is simple. According to the degree of dehydration, as estimated clinically, 1000 to 2000 cc. of fluid are administered parenterally, in addition to the 3500-cc. requirement for the twenty-four hours.

*Cases in which dehydration is severe but renal function is adequate.* These patients have experienced water deprivation for longer periods or have lost large quantities of fluid by vomitus, diarrhea or fistulas. The principles of parenteral fluid therapy are the same as those for the preceding group, but larger volumes of fluid are required. Such patients may have lost as much as 6 per cent or more of their body weight in water, and this must be replaced in addition to the basic requirement of 3500 cc. It is not uncommon, therefore, for a patient who is severely dehydrated to require 7000 cc. or more of fluid in twenty-four hours. Most of this may be given in the form of 5 per cent dextrose in distilled water, but enough of it must be in the form of physiologic saline to provide a daily minimum of 8 or 10 gm. of sodium chloride and to replace fluid lost through vomiting and diarrhea, volume for volume.

Acute severe dehydration of short duration is accompanied by the signs of hemoconcentration

described above. In such cases, care must be taken to avoid too rapid administration of fluid to obviate overloading the heart by sudden dilution of the blood, which might otherwise ensue. It may thus require as long as ten or twelve hours to administer the full complement of fluid for twenty-four hours in a severely dehydrated patient. It must be emphasized that when dehydration has been of long standing, or when for other reasons the anhydremia is accompanied by loss of plasma protein and red blood cells, the blood volume is to be restored, not by means of solutions of crystalloids, but rather by means of whole blood or blood plasma. In such cases, the administration of crystalloid solutions often initiates hypoproteinemia, not only by dilution of the blood but also by actual loss of protein from the capillary bed.

*Cases in which dehydration and impaired renal function coexist.* Severe dehydration is known to have profound effects on both the structure and the function of the kidneys. Thus, red blood cells, casts and albumin are not uncommonly found in the urinary sediment of such patients. In addition, there is often nitrogen retention of considerable magnitude in the blood. Yet, when the renal effects are secondary to dehydration resulting from other causes, the treatment is hardly more difficult than that described for the last group above. Renal function is usually promptly restored by the administration of fluid in the form of dextrose solution. This has special value in combating the ketosis and acidosis that such patients often exhibit. Not only are water and carbohydrate thereby supplied to restore to normal the metabolism of the ketogenic substances, but proteins are spared from catabolism so that the necessity for eliminating nitrogenous products and nonvolatile acids is decreased.

The cases of dehydration due to or complicated by chronic disease of the kidneys are the most difficult to treat. It is in this group that patients with hypertrophy of the prostate and urinary retention fall. Study of these cases makes one realize the important work the kidneys perform in regulating the pattern of osmotically active ions in the blood.

The first consideration in the treatment of such patients is restoration of the blood volume to as nearly normal as possible. Unlike the cases in the two groups described above, these patients usually show no laboratory evidence of hemoconcentration. The red-cell count, the hematocrit and the specific gravity of the blood may be quite normal. Yet the skin and mucous membranes are dry, there may be acetone on the breath and in the urine, and study of the blood electrolytes may show base depletion and acidosis. While prepara-

tions are being made for relieving the urinary obstruction, therefore, these patients should receive 500 cc. or more of blood plasma, or of whole blood if there is anemia or if plasma is not available. Further restoration of fluid balance is accomplished by the administration of crystalloid solutions, and the choice of fluid depends in large measure on the characteristics of the blood electrolyte disturbance.

In contrast to the almost invariable finding of a lowered total-base concentration in the plasma of patients with dehydration and renal insufficiency, the concentration of the chloride ions may be increased to well above its normal value. This, of course, implies a drop in the concentration of the bicarbonate ions and a lowering of the alkali reserve. After the blood volume has been restored by transfusion, the next step is to induce a diuresis by the slow injection of glucose solution (1000 cc.) followed by glucose in physiologic saline solution. These solutions are alternated until the total desired volume for the twenty-four-hour period has been attained. The objection to using dextrose solution alone is that the very production of diuresis in hyposthenuric kidneys causes salt wastage and further depletion of base. Furthermore, it appears impossible for such kidneys to excrete chloride and retain base. Acidosis thus persists in spite of saline infusions, and when the diminution in alkali reserve has become sufficiently severe, these form the ideal cases for the administration of sodium bicarbonate or of sodium lactate (Hartmann-Senn solution) intravenously.

Not infrequently, the depletion of total base is accompanied by loss of chloride. When the chloride concentration of the blood is sufficiently low, the bicarbonate concentration may be quite normal. The mechanism of the decreased blood chloride is often difficult to explain. Even when there has been considerable vomiting, the cause for the hypochloremia remains obscure, since patients with even slight nitrogen retention in the blood are apt to have moderate to complete achlorhydria. As in the cases with chloride retention, the first indication is to restore the blood volume by means of whole-blood or plasma transfusion. The electrolyte concentration can then be brought to normal by the administration of glucose in physiologic saline solution. Some advocate the administration of Ringer's solution in place of sodium chloride solution. The advantages of the more complex fluid are only slight. It is in this group of cases that, owing to renal insufficiency, it is easily possible to effect a higher than normal electrolyte concentration in the blood, with consequent plethora and edema. Blood-chloride con-

centrations should therefore be checked at frequent intervals. The unregulated use of dextrose solution, however, can lead to equally distressing complications. The diuresis incident thereto washes base from the blood and leads to further depletion, and in addition there is actual loss of protein from the blood stream.

These urologic problems in dehydration are frequently complicated further by heart failure and peripheral edema. The same general principles outlined above still hold. The choice of fluids is based on the same principles, but the administration should be slower and the total volume of fluid should be curtailed until cardiac compensation has been restored. When diuresis begins, however, as a result of cardiac improvement due to bedrest or digitalis, fluids should be urged rather than restricted, to avoid the concentration of waste products in the tissue fluid and blood (uremia), which may result when the kidneys are unable to concentrate urine beyond the specific gravity of 1.010.

The preceding discussion has implied that fluid replacement therapy is accomplished entirely by vein. But fluid may be administered subcutaneously as well as intravenously when there is no peripheral edema. It is customary to use 4 rather than 5 per cent solutions of dextrose for subcutaneous injection. The injection of more than 2000 to 2500 cc. a day by the subcutaneous route, however, is seldom necessary. When co-operation is possible on the part of the patient, the fluid intake by mouth may be supplemented by the rectal administration of tap water, glucose solution or physiologic saline solution.

Finally, it should be emphasized that the best method of administering fluid is to encourage the patient to take it by mouth whenever possible. To overload the stomach in an effort to avoid parenteral administration of fluid, however, is a sad commentary on clinical judgment.

## CASE 27341

## PRESENTATION OF CASE

A thirty-four-year-old salesman entered the hospital for study.

Fifteen years before admission, the patient received a blow in his left back and felt something snap in the region of his left scapula. The part was painful on deep breathing, sneezing and coughing for three weeks, and sometime later he noticed a lack of sensation of his left hand when he dipped it in hot or cold water, at a temperature painful to his right hand. In addition an inconsistent, nonradiating, burning pain occasionally appeared in the left anterior or posterior chest, and in the left upper or lower arm. This sensation occurred at irregular intervals, lasted seconds to minutes, and varied in location. The patient visited the Out Patient Department, where a loss in tendon jerks and a decrease in pain and temperature sense were noted in the left arm. He was studied thoroughly, and since no organic cause was found to account for the condition, it was considered to be hysterical in origin. Over the fifteen years prior to admission, there was no appreciable change in the patient's symptoms, although pain sensation returned in some degree to his left hand. Immediately before entry, the patient was subjected to a routine examination for employment, and a mediastinal mass was demonstrated by x-ray film. At no time had there been cough, hemoptysis or weight loss.

Physical examination was entirely negative except for diminished pin and temperature sensations over the left arm and hand; this was too vague in its distribution to be mapped out. All tendon reflexes were absent in the left arm, but present in the right.

The temperature, pulse and respirations were normal.

Examination of the urine and blood was negative. A blood Hinton reaction was negative. Findings on lumbar puncture were normal, and a spinal-fluid Wassermann test was negative.

X-ray films of the chest showed a soft-tissue mass, 7.5 by 6.5 cm., at the posterior aspect of the left chest close to the fifth, sixth and seventh ribs. The fifth rib showed a pressure defect on

its lower border, and the sixth rib was flattened and widened in the region of the mass, the changes in the flattened portion being interpreted as an old, healed fracture. The rest of the chest showed no abnormalities.

An operation was performed.

## DIFFERENTIAL DIAGNOSIS

DR. THEODORE L. BADGER:\* May we see the x-ray films?

DR. AUBREY O. HAMPTON: The lateral views are not here. I think we can accept the interpretation of the size and location of the soft-tissue mass. You can see the upward concavity of the fifth rib, which looks as though it had been pushed up by pressure, and the enlargement of the sixth, with definite alteration in structure; there is no

FIGURE 1.

deformity of the seventh (Fig. 1). Within this mass, there are flocculent areas of calcification, not mentioned in the report.

DR. BADGER: There is no evidence of bone destruction so far as the vertebra is concerned?

DR. HAMPTON: I do not believe so, but the vertebrae are not well seen. The mass is close to the spine. One might expect it to be eroded by pressure just as this rib is. I might say that this appearance in the rib is not by any means typical of a healed fracture.

DR. BADGER: Summarizing the case briefly, we have a man who, following a blow in the left back fifteen years before admission, developed secondary symptoms in the left arm, which have recurred from time to time up to the present, essentially without change in character. In the present illness, these symptoms were fleeting pains that

\*Instructor in medicine, Harvard Medical School, chief of Thoracic Clinics, Boston City Hospital.

came and went in the left arm, loss of tendon jerks, and loss of sensation to cold and heat, symptoms that are almost identical to those noted fifteen years previously. At that time, no definite cause for the neurologic findings was discovered.

Do you know whether an x-ray film was taken at the time of the blow?

DR. RALPH ADAMS: No x-ray film of the chest was taken.

DR. BADGER: The important features really boil down to what was apparently a fracture of the left sixth rib when the patient received the injury. He had pleuritic pain on cough, sneezing and deep breathing, consistent with fracture of a rib. We do not know the severity of the blow. The symptoms and physical findings have not changed in any way. The neurologic findings, which were extremely vague, were the same at the time of the injury as they were at admission. The areas with loss of pin sensation are not accurately demonstrated. No mention is made either of atrophy of the hand or of differences in the two pupils, and Horner's syndrome was apparently not present. Therefore, I am at a loss to know whether this left-arm syndrome is definitely to be connected with the original trouble. Clinically, the patient was well, with no symptoms except in the left arm and hand. He was being examined for a new job. The laboratory findings were entirely negative. Had it not been for the x-ray picture, I gather there would have been no discovery of the underlying pathologic lesion.

This mass shows some calcification in its center, the left sixth rib is definitely abnormal, and there is a pressure distortion of the fifth rib posteriorly. The differential diagnosis in this case revolves around the character of the tumor mass. It seems unlikely that the tumor was malignant, because it would be unusual for a malignant tumor to be present fifteen years without more significant changes, although we might find malignant changes developing late in a primary benign tumor.

But if it was a benign tumor, how are we going to account for it? It occurs to us at the start that a severe blow in the back with considerable pain and with symptoms indicative of fracture might have had something to do with it. We wonder whether this was an unusual hematoma resulting from the fracture, which had never been observed and which had calcified over a period of years without significant change in size. That would to some extent account for the picture presented. There appears to be no definite evidence

of an aneurysm. The signs are not consistent with it. The arch and descending aorta were normal, and the spinal-fluid Wassermann test was negative. Dermoids and teratomas are more likely to be seen in the anterior chest, and I believe they can be ruled out. Lymphosarcoma or Hodgkin's disease was probably not responsible.

If the mass was in any way associated with the symptoms, which persisted for years, we find ourselves reduced to three possibilities. If the mass was associated with the original injury, it should be a benign tumor—either a hematoma or a neoplasm of slow growth. Chondromas are likely to be posterior tumors in the upper portion of the chest and might be related to the bone injury. The x-ray findings were not quite characteristic of chondroma, but I think it could have been that, and the pressure symptoms for a long period of time might in part have been due to such a tumor. We must also bear in mind the possibility of neurofibroma. So far as benign tumors are concerned, neurofibroma is probably a good bet for explaining symptoms over a long period—an entirely benign tumor presenting no symptoms except neurologic ones, explainable on the basis of neurofibromatous involvement of some portion of the nerve roots. If the tumor involved the first, second or third rib, I should be more inclined to account for the neurologic symptoms, on the basis of pressure or invasion, than I am able to in the location where it actually occurred. There appeared to be no involvement of the sympathetic chain, for there is no comment about alterations in the left pupil. Also, there was no apparent atrophy of the left hand. In fact, I am a little confused about the neurologic findings: they were constant so long and yet produced no secondary changes. I am, therefore, inclined to divorce the neurologic findings from the underlying lesion in the chest and to believe that they may be explained on some other basis.

I think that this is a benign tumor, and I name chondroma, calcified hematoma and neurofibroma, in that order, as the most likely possibilities.

DR. DONALD S. KING: I saw this patient once in the Thoracic Clinic. We put neurofibroma first, with secondary changes in the ribs from pressure. Our opinion had been changed at the time the surgeons operated, but that was our original impression.

DR. CHARLES S. KUBIK: Have we ever had a neurofibroma with calcification?

DR. HAMPTON: We have had a ganglioneuroma, with calcification and secondary involvement of the ribs, but not like this. This rib should have

given us more pause. The X-ray Department made a diagnosis of neurofibroma. I do not know whether they changed later or not.

DR. WYMAN RICHARDSON: Do you have to think of vascular tumors—hemangioma and so forth?

DR. HAMPTON: The widened rib and the change in structure should make one suspect a primary bone tumor. It could be a vascular tumor, or an osteochondroma; and we have a few cases of bone changes similar to that in vascular neurofibromas. I do not know how content we should be with any diagnosis, but I think Dr. Badger's reasoning is a little better than ours.

DR. EDWARD D. CHURCHILL: I think we were a little hasty in attributing the changes in the ribs to the pressure of a neurofibroma. A neurofibroma arising from the intercostal nerves gives extreme deformity of the ribs. They look nothing at all like these ribs. They are thin, keel-like structures, completely surrounded by slowly growing tumor. All of us who saw this man made a provisional diagnosis of neurofibroma. I wish Dr. Kubik would tell us just how this tumor is destroying the tendon reflexes in the left hand.

DR. KUBIK: I cannot explain it any more than Dr. Badger could. The tumor is not in the right place to do so, and perhaps one cannot assume it was present for fifteen years, or from the time that the patient first observed neurologic symptoms. It obviously could not have been hysteria if the tendon reflexes were gone. The findings suggest more than one lesion, and therefore favor neurofibroma. There may be another lesion, possibly intraspinal, although the lumbar-puncture and spinal-fluid findings do not suggest that, in fact are rather against it.

DR. HAMPTON: Osteochondromas are also multiple.

DR. KUBIK: I should not have thought of neurofibroma, because of the calcification, which I cannot remember having seen with neurofibroma.

DR. ADAMS: Dr. King's note from the Thoracic Clinic reads, "The x-ray findings are characteristic of neurofibroma with rib changes, but no erosion; Dr. Churchill strongly inclines toward surgery." At operation, the sixth rib was densely adherent posteriorly and grossly deformed by intrinsic tumor. The rest of the tumor was found lying in the costovertebral gutter, with the left sympathetic chain forced backward over its posterior aspect and closely adherent. The tumor stopped abruptly at the head of the rib. The pleura could be separated from its attachments without profuse bleeding. The tumor seemed to be composed of irregular bony fragments, which

felt like a bag of gravel. I thought at that time that the preoperative diagnosis of neurofibroma should be changed to chondroma. The tumor was easily removed, and the patient made an uneventful recovery.

#### CLINICAL DIAGNOSIS

Neurofibroma.

#### DR. BADGER'S DIAGNOSIS

Chondroma of the lung, or  
Calcified hematoma in the region of the posterior end of the sixth left rib, or  
Neurofibroma.

#### ANATOMICAL DIAGNOSIS

Cavernous hemangioma of the left sixth rib.

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: An interesting phenomenon, which was apparent as soon as the tumor was removed, was that the resected specimen was only half the size of the specimen in the body, as judged by the x-ray films. In other words, it had shrunk 50 per cent during resection, and the reason became obvious as soon as we cut across it. It consisted of a great mass of dilated blood vessels, with small spicules of bone between them. Its gross and microscopic appearance was characteristic of a cavernous hemangioma.

DR. HAMPTON: Was there no neurofibromatous tissue in it? It could not be called a vascular neurofibroma?

DR. MALLORY: No.

DR. MAURICE FREMONT-SMITH: Has anything happened to the neurologic symptoms?

A PHYSICIAN: No; we have not yet explained the symptoms in his arm except to guess they were due to the proximity of the tumor to the sympathetic chain.

DR. KUBIK: I do not see how that could be the explanation, but the patient may have had another hemangioma, perhaps a very small intraspinal one, which would not necessarily produce any spinal-fluid changes.

---

#### CASE 27342

#### PRESENTATION OF CASE

A fifty-three-year-old housewife was admitted to the hospital in a semicomatose condition.

Two weeks before admission, the patient was taken ill while in Florida with general malaise and fever of 99 to 102°F. Her condition was diagnosed and treated as "grippe," and the pa-

tient apparently improved, since she was able to ride home by automobile three days later, arriving home one week before admission. During the next two days, she felt well enough to do some housework, but four days before admission she again had general malaise and fever of 102°F. The following day, she developed a slight cough and a stiff neck, and her temperature was 101°F. She was seen by her physician, who found nothing on physical examination except a stiff neck. The day before admission, she felt much better, and her temperature remained normal. On the day of admission, fever recurred, reaching 105.6°F. A sputum examination showed large numbers of Type 8 pneumococci. A white-cell count was 19,000 with 84 per cent polymorphonuclears. The patient was given two 15-gr. doses of sulfathiazole, and in the evening, after being seen by a consultant, was given 30 gr. more and then admitted to the hospital.

The patient had had measles, followed by pyelitis, ten years before admission.

Physical examination showed a well-developed and well-nourished, semicomatose woman who was mumbling slightly, with rare coughing spasms, and who resisted being disturbed. The skin was dry, and the pupils were equal and regular and reacted to light. There was slight but definite rigidity of the neck. The heart did not appear to be enlarged. The sounds were of poor quality, but regular; there were no murmurs. The lungs were clear throughout. The abdomen was soft; no masses were felt. The reflexes were normal throughout. The blood pressure was 84 systolic, 56 diastolic.

The temperature was 105.6°F., the pulse 140, and the respirations 40.

Examination of the blood showed a red-cell count of 5,400,000 with a hemoglobin of 85 per cent, and a white-cell count of 18,000 with 84 per cent polymorphonuclears. Eighteen hours after admission, the white-cell count had risen to 30,000. A catheter specimen of urine showed a specific gravity of 1.028, a + test for albumin and some white blood cells and many finely and coarsely granular casts. A blood culture was negative. The nonprotein nitrogen of the blood was 55 mg., and the blood urea nitrogen 29 mg. per 100 cc. A lumbar puncture showed normal dynamics, and the spinal fluid was normal. A Widal test was negative, and cultures of the stools were negative for typhoid and dysentery organisms. An x-ray film of the chest, taken with a portable machine, was negative.

On admission, the patient was given 5 per cent glucose and physiologic saline solution by clysis,

and subsequently, intravenous, rectal and subcutaneous fluids to maintain a daily intake of from 2000 to 3000 cc. Sulfathiazole, 15 gr. every four hours, was continued for the first eighteen hours of the hospital stay but was then omitted. The patient gradually became more responsive, and about twenty-eight hours after admission the temperature had dropped to 101°F. and gradually from there to normal. The pulse dropped only to 110, and the respirations to 25. During the first twenty-eight hours, the urine output by catheter was only 120 cc., but it was believed that the patient voided unmeasured amounts with coughing and with bowel movements.

On the third day, the patient was talkative but very weak. The blood pressure was 86 systolic, 48 diastolic. The cough had become less frequent, but the diarrhea continued. During the next two days, her blood pressure continued to be low but her cough and diarrhea almost disappeared. On the sixth day, the abdomen was slightly distended and tender in the right hypochondrium. Catheterization yielded 400 cc. of dark turbid urine containing many white blood cells and casts. The next day, the temperature was normal and the pulse 104, but the patient became very lethargic. There was persistent tenderness in the right hypochondrium, and bilateral ankle clonus was found. On the eighth day, she could be roused very slightly; catheterization yielded only 100 cc. of urine in eighteen hours, after an intake of 3000 cc. The patient was given an ampule of 50 per cent glucose solution intravenously. The nonprotein nitrogen of the blood rose to 80 mg. per 100 cc., and the following day, immediately after catheterization,—only 100 cc. of urine had been obtained in the previous fifteen hours,—she had sudden respiratory failure and expired.

#### DIFFERENTIAL DIAGNOSIS

DR. EARLE M. CHAPMAN: Why should an apparently healthy woman of fifty-three years have a minor illness in Florida and then come home to die in anuria about ten days after the return of symptoms?

The illness in Florida was called "grippe," but a sudden fever of 102°F. at least suggests that she might have had malaria. However, there are several points that I should like to rearrange to fit a clinical pattern consistent with an acute infection in the urinary tract. First is the fact that she had pyelitis ten years before admission—a disease known to recur when people suffer fatigue and dehydration. Certainly, the environment in Florida and during the drive back home was conducive to both factors. Likewise, the ir-

regular fever, the high white-cell count and the vague symptoms are compatible with pyelitis or even pyelonephritis. Unfortunately, there is no report of the urine at this period of her illness.

Evidently, the single finding of a Type 8 pneumococcus in the sputum led her physician to suspect a pulmonary infection. Although Type 8 ranks about the fifth or sixth most frequent type found in persons with pneumonia, it could well be a harmless inhabitant of the nasopharynx in a person returning from Florida to a New England winter.

With a suspected pulmonary infection and with stiffness of the neck and a semicomatose condition, one thinks of a brain abscess secondary to a diseased lung. Again, we cannot substantiate any such diagnosis by physical examination, chest x-ray film or lumbar puncture; and, of course, we know that sulfathiazole is poorly concentrated in the cerebrospinal fluid and is therefore contraindicated in cases of meningitis or brain abscess.

After receiving 4 gm. (60 gr.) of sulfathiazole, the patient was much worse and was admitted to the hospital in rather poor condition. She was comatose, coughing and behaving in a peculiar manner. There is no description of the scleras or conjunctivas. It is significant that she already had nitrogen retention and a urine containing albumin, white blood cells and granular casts. Adequate fluids were given, but still she did not excrete a proper quantity of urine. Something was evidently wrong—the sulfathiazole was stopped after a total of 8 gm. had been given in a period of about forty-eight hours. Then she seemed to improve, and the temperature returned to normal. However, the pulse continued to be rapid, and the blood pressure became even lower in its maintained or diastolic level. Then there was a cessation of the diarrhea—which explains the need of the previous laboratory studies that were negative.

The signs of kidney failure increased—the urine became turbid and dark and contained many white blood cells. Congestive failure, or some toxic effect, caused distention and tenderness of the liver. Lethargy, drowsiness and coma supervened, and the nonprotein nitrogen reached 80 mg. per 100 cc.; yet the blood pressure remained low. Concentrated glucose did not bring about a diuresis. She died of sudden respiratory failure. I doubt that she had a silent occlusion of a coronary artery as a cause of this.

It is my belief that the patient died in anuria because her kidneys, previously diseased and possibly showing pyelonephritis, did not excrete sulfathiazole properly. It would be helpful to know

the blood level of the drug for the several days after it was stopped. Sulfathiazole is definitely more toxic to the kidneys than the other sulfonamide drugs are. It seems that the kidney tissue was particularly sensitive in this woman, since we have no description of the commonest signs of toxicity—an erythematous skin lesion or reddened conjunctivas. The fever, leukocytosis, diarrhea and mental changes could be part of the reaction. I am not surprised by the absence of anemia. The stiffness of the neck does concern me, and unless we call it meningismus, I cannot explain it.

From reported cases of anuria caused by sulapyridine and sulfathiazole, we know that the chief difficulty is with a plugging of the collecting tubules, or even the ureters at any level, by the drug crystals and secondary detritus. Consequently, microscopic sections have shown great distention and plugging of the tubules, while the glomeruli remained comparatively normal. If such a plugging had occurred in this case, we could expect that cystoscopy and ureteral lavage would have been therapeutically effective.

DR. FLETCHER COLBY: That seems to be a good possibility. On the other hand, is it not quite possible that she just had chronic nephritis of such severe degree that a superimposed acute infection was enough to produce anuria without implicating sulfathiazole?

DR. ALFRED KRANES: The specific gravity of 1.028 is somewhat against chronic nephritis.

#### CLINICAL DIAGNOSIS

Bronchopneumonia?

#### DR. CHAPMAN'S DIAGNOSES

Chronic pyelonephritis.

Sulfathiazole toxicity, with plugging of ureters and tubules of the kidneys, leading to anuria.

#### ANATOMICAL DIAGNOSES

Acute pyelonephritis, bilateral.

Pericarditis, acute.

Myocarditis, acute.

Pulmonary edema and congestion.

Ascites, slight.

#### PATHOLOGICAL DISCUSSION

DR. BENJAMIN CASTLEMAN: This patient was studied at another hospital, but the autopsy was performed by one of our laboratory staff. Clinically, because of the finding of the Type 8 pneumococcus in the sputum, a great deal of attention was paid to her chest, and it was believed that she

probably had bronchopneumonia. The autopsy, however, showed no evidence of pneumonia, just a little edema and congestion of the lungs. Her kidneys were large, weighing 385 gm. The capsules stripped fairly easily, and the surfaces showed a reddish mottling and few grayish-white spots that suggested small abscesses. The sections microscopically showed a diffuse acute pyelonephritis. The tubules were filled with red and white cells, and there were a number of small abscesses throughout the kidney. We specifically looked for sulfathiazole crystals and could not find any, either grossly or microscopically. The severe degree of pyelonephritis, however, was enough to have produced the renal insufficiency. We have

had this year, I believe, four cases of acute pyelonephritis, very similar to this, in which the signs and symptoms did not particularly point to the kidney. The only clue here was the presence of leukocytes in the catheterized specimen. Unfortunately, the urine was not cultured. There was about 50 cc. of turbid fluid and a few shreds of fibrin in the pericardial cavity, and sections of the myocardium showed a few collections of polymorphonuclears. Bacteriologically, we were able to grow nonhemolytic streptococci from the kidney and spleen.

DR. JOHN H. TALBOTT: Did the patient have a cerebral abscess?

DR. CASTLEMAN: The brain was not examined.

## MATERNAL WELFARE AND THE NATIONAL EMERGENCY

World War II is inevitably forcing the country to face a national emergency in maternity care. Already the armed forces have taken large numbers of physicians into service, and future estimates call for nearly half of today's active practitioners. This need must be met. But equally so, maternal care must not be jeopardized. The totalitarian countries have been quick to realize this, for their armies of the future can exist only in the babies of today. To them, the mother and her child are irreplaceable assets. One must hope that in lands granted the opportunity of building for a peaceful, productive future, maternal welfare will be no less zealously guarded.

The problem in this country is not a new one. Ever since the introduction of routine prenatal examinations in the early years of this century, more and more attention has been paid to organized maternal care. The result has been a gratifying but by no means satisfactory reduction in maternal deaths and morbidity. Even in 1939, there were over 12,000 live births without medical attention. Less fortunate still were those women cared for by practitioners of meddling obstetrics. It is clear that further decrease in mortality and morbidity rates will come only through an improvement in the quality of obstetric care and in its extension to the entire population. Ideally this should be provided by a sufficiently large number of physicians well trained in obstetrics. An all-out program of this sort would include a more thorough undergraduate obstetric training, adequate postgraduate educational opportunities, adjunct obstetric nursing services, improved hospital facilities, lay education, consultation services, and an organization of medical facilities to bring all economic and geographic units within the scope of the program. Thus, every pregnant woman would be cared for by a physician basically well-trained in obstetrics, with all possible specialized assistance at hand whenever needed. This goal has never been reached; when it may be attained in the future one cannot foretell. With the removal of ever-increasing numbers of physicians from civilian life the date will be further postponed. But the problem is one of the immediate present. In solving it, America might do well to turn to the midwife. Her help now and in the reconstruction to follow would be invaluable; it is probable that in certain capacities she would become part of the permanent obstetric service of the nation.

Although the midwife never has been much favored in the United States, she still delivers more than half the babies of Europe. She has played her part in the notably low mortalities of the Netherlands and Scandinavia. Midwifery services in the United States as well have demonstrated that they can offer safe pregnancy care. The Frontier Nursing Service of Kentucky covers

seven hundred square miles of territory in mountainous Leslie County and has delivered over 3000 babies, with a gross uncorrected maternal mortality of 0.68 per 1000 live births—the mortality rate for the country as a whole approximately 4 per 1000. The Philadelphia Wives Service shows a mortality rate of half of the city as a whole. Louisiana has reduced its maternal mortality significantly through obstetric care offered by its colored midwives. The Outpatient Department of the Boston Lying-in Hospital, manned by externs, has a rate of 0.15 per 1000 home deliveries: this and similar departments elsewhere are basically midwifery services. It must be noted, however, that these results have been obtained only with carefully and rigidly controlled systems under competent medical supervision, with proper hospital facilities in the background. Furthermore, it is clear that the best figures come from the services staffed by the modern type of midwife.

The new order of midwife is a graduate nurse who has had additional formal training in obstetrics. In training, therefore, she stands between the obstetric nurse and the obstetrician. She may hold the certificate of the Central Midwives Board of Great Britain or be a graduate of the Lobenstein School, of New York City, or of the newly founded school of the Frontier Nursing Service; she will undoubtedly find other schools offering similar courses. She is licensed as carefully as the physician. Over her and working with her are competent consulting obstetricians, and always there is access to a hospital. Cases are registered early with her service and are selected according to anticipated difficulties. Patients with complications are hospitalized before they become serious problems. Emergencies are

ects to which the institute can address itself. The city dweller is well protected against polluted water, infected food and incompetent systems for sewage disposal, but he is allowed less sunlight, is forced to inhale more foreign materials, is exposed to a greater variety of respiratory viruses and probably subjects himself to a greater and more frequent climatic variation than does the man on the farm. The health authorities of all our large cities are also now concerned with housing, with transportation facilities, with transient populations and with an ever widening field of application for the knowledge and understanding of environment.

Starting out with a relatively modest budget, the institute will have a splendid opportunity to prove itself. Provisions have been made for it to receive and accept grants, gifts, bequests and contributions from private citizens and foundations. Its future scope is thus not limited or altogether dependent on the expediences or political necessities that have been known to cramp many other governmental enterprises. If the largest city in the world finds that a public health research institute is of value, other cities will surely follow suit, for the largest city has no monopoly on municipal problems concerned with the health and welfare of the citizens. It is hoped that this new type of research motive will prove successful.

## MEDICAL EPONYM

### JOFFROY'S SIGN

'Nature et traitement du goitre exophtalmique [The Nature and Treatment of Exophthalmic Goiter]' was the subject of a lecture delivered by Alexis Joffroy (1844-1909) in December, 1891, in the neurological clinic of the Hospice de la Salpêtrière. This lecture appears in *Progres médical* (18: 477-480, 1893). A portion of the translation follows:

*Paralysis of the muscles of the upper part of the face.* In our patient, these muscles were affected in a peculiar way that I have seen previously in three other cases although this peculiarity has never been pointed out before. It is as follows: if a person who is looking downward is asked to look up at the ceiling quickly, holding his head still, it will be found that as the eye balls roll upward, the eyebrows are raised and the forehead wrinkles. We have here a synergic movement occurring in the normal state that does not occur in this patient. Her eyebrows and forehead remain abso-

lutely immobile, even when she tries very hard to look upward.

### SECTION OF OBSTETRICS AND GYNECOLOGY\*

#### FATAL SEPSIS FOLLOWING ABORTION

A twenty seven year-old para V, approximately three months pregnant, was admitted to the hospital with a high temperature and with a catheter protruding from the vagina.

The past history contained no pertinent details. The patient had apparently had no prenatal care. Physical examination was essentially negative except for the elevated temperature, a corresponding rise in pulse rate, and tenderness and spasm over the entire lower abdomen. The patient was having cramplike pains, and a few hours later delivered herself spontaneously of a macerated fetus and the placenta. Following delivery, she had a chill, which lasted ten minutes. The temperature ran a high septic course, and the patient developed jaundice. The treatment consisted in several transfusions, the uterus being left entirely alone. Death occurred on the eleventh day after admission.

Autopsy revealed extensive jaundice, the uterus was necrotic from the cervix to the fundus, the spleen was enlarged to twice its normal size, the left ovary and tube were necrotic, and the right ovary and tube were infected.

*Comment.* There is nothing in this history to reveal whether this was a criminal abortion or one brought on by the introduction of a catheter by the patient herself. When she arrived at the hospital, she was septic, and she died of profound sepsis ten days later. The jaundice was characteristic of that sometimes associated with infection, and the infection of the uterus, tubes and ovaries was typical of the sepsis that often follows abortion. This death occurred before the introduction of the sulfonamide drugs, and it is possible that intensive chemotherapy might have averted this death.

As in many of these cases, this patient was probably treated by an abortionist. The end result is one that may follow any criminal abortion—a tragedy that, if generally recognized, might prevent some women from looking on this procedure with perfect nonchalance.

\*A series of selected case histories by members of the section will be published weekly. Comments and queries by subscribers are solicited and will be discussed by members of the section. Letters should be addressed to Dr. Raymond S. Titus, Secretary, 350 Dartmouth Street, Boston.

DEATHS

ALBEE — GEORGE M. ALBEE, M.D., of Worcester, died August 10. He was in his seventy-first year.

He received his degree from the New York University Medical College in 1893, and had practiced in Worcester for many years, having been particularly interested in cardiology.

Dr. Albee was a fellow of the Massachusetts Medical Society and the American Medical Association. He was also a fellow of the American College of Physicians, and a member of the New England Heart Association and the American Heart Association.

LORD — WILLIAM O. LORD, M.D., of New Bedford, died August 8. He was in his sixty-first year.

Born in New Bedford, he received his degree from the Columbia University College of Physicians and Surgeons in 1903.

He was a member of the Massachusetts Medical Society and the American Medical Association.

His widow, a son, a half-brother and two half-sisters survive him.

REPORT OF MEETING

NEW ENGLAND PATHOLOGICAL SOCIETY

A regular meeting of the New England Pathological Society was held on April 17, Dr. Traey B. Mallory presiding. Dr. Arthur Purdy Stout, associate professor of surgery at Columbia University and attending surgical pathologist to the Presbyterian Hospital in New York City, spoke on "Tumors of Peripheral Nerves." Dr. Stout divided the tumors of the peripheral nerves into six groups (Table 1), and the discussion dealt chiefly with

this mesectoderm forms adult connective tissue and cartilage.

These observations form a solid foundation for the hypothesis that most of the primary nerve-sheath tumors are of neurectodermal origin and composition. They explain the connective-tissue fibers of the neurilemmoma, neurofibroma and malignant neurilemmoma (schwannoma) and the bone and cartilage of the teratoid tumors of peripheral nerves. Further confirmation comes from the fact that Dr. Murray has grown almost pure cultures of schwannian cells from neurilemmomas and neurofibromas and from one case of malignant neurilemmoma (schwannoma). The formation of adult ganglion cells by ganglioneuromas and of true rosettes by neuroepitheliomas establishes their neurectodermal origin. The neurectodermal origin of the pigmented skin tumors is suggested by the observations of Masson and Laidlaw, but the speaker did not accept it as proved.

According to Dr. Stout, primary neoplasms of purely mesodermal origin include hemangiomas and lipomas. Whether ganglions, neuroxanthomas, fibromas and so-called "neurogenic sarcomas" are true nerve-sheath tumors of mesodermal origin is open to debate. He denied that there is adequate proof that ganglions (similar to the familiar ganglions of the wrist), fibromas and xanthomas ever grow in or from peripheral nerves. Proof is also lacking that any of the malignant spindle-cell tumors that form connective-tissue fibers and grow in or from the peripheral nerves are of mesodermal origin. Therefore, until such proof is forthcoming, the use of the term "neurogenic sarcoma" is not justified.

The discussion was opened by Dr. Orville T. Bailey, who confessed his bewilderment concerning the histogenesis of the nerve-sheath tumor. He believes that new methods of study must be developed before any decision can be made; he stated that the work of Dr. Stout and

TABLE 1. Tumors of Peripheral Nerves.

NON NEOPLASTIC NEURECTODERMAL TUMORS	MESODERMAL NEOPLASMS
Traumatic or amputation neuroma	Hemangioma
Spontaneous neuroma	Lipoma
Appendiceal neuroma	(Ganglion?)
	(Neuroxanthoma?)
	(Fibroma?)
	("Neurogenic [neurogenous] sarcoma"?)
NEURECTODERMAL NEOPLASMS	TUMORS AND LESIONS WHOSE GROWTH IS INDUCED BY
Neurilemmoma	NEUROGENOUS TUMORS
Neurofibroma	Fibroma molluscum
Ganglioneuroma	Multiple adenoma sebaceum
Neuroepithelioma	Elephantiac hypertrophy of bone, intestine,
Malignant neurilemmoma	appendix and so forth
Teratoid tumor	Hypertrichosis
(Pigmented mole and melanoma)	Skin pigmentation
(Mesectodermoma?)	Multiple lipomas
NEOPLASMS COMPOSED OF MULTIPLE TISSUES OF WHICH	SECONDARY NEOPLASMS
NEURAXONS FORM ONE IMPORTANT ELEMENT	Direct extension within nerve sheath
Glomus tumor	Intra-neural metastasis
Cutaneous leiomyoma	Tumors of ganglia lying within nerves

the question of the cellular origin and the composition of the primary neoplasms. The work of Masson and Nageotte and the tissue-culture observations of Dr. Margaret Murray suggest very strongly that the dominant tissue of the nerve sheath is the neurectodermal schwannian syncytium. This grows in a characteristic fashion in vivo and in vitro, and can form reticulin fibers. The fact that the schwannian cells of the nerve sheath can form connective-tissue fibers need cause no surprise, since it is well known that the cells of the neural crest form connective tissue (mesectoderm) in the human embryo. In urodeles,

Dr. Murray had opened up new possibilities that may do a good deal toward clarifying the situation. He pointed out that there is one problem, without the solution of which one cannot consider the problem of histogenesis completely solved — namely, the occasional resemblance of nerve-sheath tumors to meningiomas. Of course, both types of tumor vary a good deal in histologic structure, and if one acquires a large series of both tumors and arranges them in a graded series, the two extremes are very different; there is an overlapping stage, however, indicating that somehow or other the problem

of the histogenesis of the two is related. Also, the appearance of multiple meningiomas in patients with multiple neurofibromatosis is another indication of their possible relation. If one has only a small fragment of tissue to examine, it is possible to find areas that are almost entirely composed of schwannian cells in the gangliogliomas occurring outside the central nervous system. The occurrence of these areas was very striking in a case reported by Cushing and Wollbach some time ago, in which the diagnosis for a long time was obscured by this difficulty. Dr Bailey believes that the description of the neuroxanthoma suggests strongly that one of the forms of sclerosing hemangiomas is involved. Some hemangiomas are associated or occur in the immediate vicinity of pigmented nevi, and the formation of giant cells and lipid phagocytes is a part of the sclerosing process that goes on in many hemangiomas. Furthermore, this explains very well the histologic appearance of infiltration. The hemangioma has not infiltrated surrounding tissue, but adjacent connective tissue has been stimulated to form its stroma. The glomus tumors, according to Dr Bailey, include a large number of nerve fibers that are the integral part of the tumors themselves. In addition, they have glomus cells that appear to be derived from the smooth muscle elements of the normal glomus. The combination of these fibers and cells not only results in a complex tumor from the morphologic point of view but actually takes on the function of a gigantic glomus.

Dr Stout commented on Dr Bailey's discussion and said that Dr Murray had also been attempting a study of meningiomas from a tissue culture point of view. There are different kinds of meningiomas, and they show quite different characteristics. Cultures of what seem to be meningeal schwannian-cell tumors resemble cultures of schwannian peripheral nerve tumors, they are otherwise quite different. Dr Murray has also had an opportunity to grow three glomus tumors, and they have been extremely interesting in tissue culture because they have grown out endothelium that could be recognized quite easily *in vitro*. They have also grown out schwannian cells, which is to be expected because there are so many nerves in the glomus tumors. Finally, they have grown out the so-called "epithelioid cells." These have done a very interesting thing in culture. When endothelium has grown out in long thick syncytial masses, the epithelioid cells of the glomus tumor attach themselves in clusters to the endothelium. Therefore, the relation of the epithelioid cells to the smooth muscle cells that Dr Bailey spoke about is very possible. Drs Stout and Murray were fortunate enough to get hold of an infiltrating glomus tumor and grow it *in vitro*, and it behaved in exactly the same way as the benign glomus tumors. Dr Stout had never before come in contact with an infiltrating glomus tumor, but apparently it was genuine.

Dr Robert Gross continued the discussion by stating that in the classification of the neuroectodermal tumors Dr Stout mentioned neurilemmoma and malignant neurilemmoma. Dr Gross believes that the malignant neurilemmomas might be further divided, because in reviewing the specimens at the Peter Bent Brigham and Children's hospitals, it was evident that some have more malignant qualities than others, so far as the clinical characteristics are concerned. He said that the benign tumors are called "neurilemmomas," the middle group malignant neurilemmomas, and the more malignant ones "neurogenic sarcomas," although he acknowledged that these terms are in correct, in comparison with their use by other pathologists. In the middle group, the findings are not the

same as those in the rank and file of sarcomas. This type of neoplasm tends to recur locally but does not metastasize. It can be recognized histologically in that the cells have more cytoplasm than those of the neurilemmoma, the fibers are shorter, the nuclei are vesicular, and they may have occasional mitotic figures. Dr Gross stated that he had seen four of these tumors. One, of the fifth nerve, was in a thirty-two-year-old woman who had recurrences in spite of five or six attempts at removal and heavy x-ray therapy. Another, in a thirty-year-old woman with a tumor of the left subscapular nerve, which was locally excised, recurred, and two years later a further excision was done. This went on for fourteen years before massive local recurrence extended into the thorax. The third patient was a child with a lesion of the little finger. The tumor recurred after six local operations, and finally ended with removal of the ulnar half of the hand. The last case encountered was that of a twenty-three-year-old man with an egg-sized tumor of the posterior cord of the brachial plexus. Since, histologically, this tumor had the same characteristics that were used for placing neoplasms in this group of malignant neurilemmoma, local excision by peeling it out from the cord was not done, but the entire posterior cord was removed. There has been no evidence of recurrence. Dr Gross considers it essential to recognize this group because of the practical considerations involved. In other words, these tumors do not need to be treated by amputation, as neurogenic sarcomas that occur in extremities do, and conversely cannot be treated properly by enucleation, as one does in a benign tumor (neurilemmoma), by peeling it out from the sheath. Therapy must lie between the more radical and conservative forms, in other words, the entire mass, with nerve trunk, must be excised.

Dr Stout admitted that the classification of malignant neurogenous tumors used is not sufficiently complete. He thinks that it is probably necessary to subdivide the malignant neurilemmomas, or schwannomas. He added that most of these, as Dr Gross had said, are malignant by infiltrative growth, and very few of them metastasize. Dr Stout is as yet unable to subdivide them into grades of malignancy.

Dr Donald Murnaghan, of Ireland, stated that a few days previously Dr Murray had very kindly shown him some of her preparations, some were living, others fixed and stained. His own experience, from studies made in the laboratory of Dr Warren Lewis in the Carnegie Institute of Washington at Baltimore, was in complete agreement with her identification of schwannian cells. He recognized the same type of cell in chick embryo and mouse embryo material and noted the similarity between them, the satellite cells of spinal ganglion cells were tentatively identified as oligodendroglial, the latter in cultures of the central nervous system. In cultures of embryonic peripheral nerves, rapid outgrowth of mesenchymal cells soon obscured the migrating schwannian cells, and he did not follow them. His experience did not extend to adult issues, and therefore he did not express an opinion on Dr Murray's work in this field, except to acknowledge her ability to distinguish schwannian cells from fibroblasts. Embryologists believe that oligodendroglia and schwannian cells arise from equivalent sources in the neural ectoderm, a term that should be used with reservations because it is now believed that the time-honored, three-germ layer is more a convenient than an accurate representation of the true state of affairs in the young developing embryo. Histologists are familiar with the similarity between spinal ganglion satellite cells and the sheath cells

of Schwann, and now cytologists find certain morphologic and cultural characteristics common to all three. He stated that oligodendroglia, the satellite cells of spinal-ganglion cells and schwannian cells, are morphologically equivalent, showing similar characteristics, embryologic, structural and cytologic. He then showed in a motion-picture film how oligodendroglia grow out in a culture of the midbrain of a seven-day chick embryo, in a fluid medium, and to indicate the method of locomotion so beautifully demonstrated by some of these cells.

Dr. Tracy B. Mallory continued the discussion. He said that a pathologist is often called on by the surgeon to give an opinion regarding therapy in local recurrence, since it is known that some tumors metastasize. Often, a patient comes in who has had one or two or even three recurrences of definite malignant types. The question comes up whether amputation or another local excision should be done. He asked Dr. Stout to say a little more about treatment, about radiation of the malignant type and also how the acoustic neuromas fitted into his classification.

Dr. Stout answered that if the tumor is a malignant form occurring in von Recklinghausen's disease, practically none have been cured either by excision or amputation. Possibly the reason for that is that von Recklinghausen's disease is a generalized disease in which many nerves are involved, and if one succeeds in removing one of them that seems to be malignant at the moment, the tendency to form malignant tumors in that patient is great enough for other tumors to form further progressive growths. When they occur without von Recklinghausen's disease, the indication is to try to get rid of the local growth. If its extent is so wide as to necessitate amputation, one should not hesitate to advise amputation. From personal experience and reading, Dr. Stout believes that none of these tumors are radiosensitive, and that none are destroyed by irradiation. The very rare neuro-epitheliomas are extremely malignant metastasizing tumors, and the most radical form of treatment is indicated.

Dr. Stout remarked that he had seen fewer acoustic tumors than tumors farther away from the central nervous system. Those that he had seen appeared to be neurilemmomas. They show some variance and have a much greater tendency to have cells containing lipoid than the peripheral tumors, in which lipoid is only occasionally found. He said that Dr. Murray has grown three angle tumors *in vitro*, and that they, too, grew out cells that were interpreted as schwannian cells.

## BOOK REVIEWS

*Radiologic Physics.* By Charles Weyl, M.S.; S. Reid Warren, Jr., Sc.D.; and Dallett B. O'Neill. With a foreword by Eugene P. Pendergrass, M.D. 8°, cloth, 460 pp., with 166 illustrations and 33 tables. Springfield, Illinois: Charles C Thomas, 1941. \$5.50.

This book deals with those branches of physics that are met with in the study and application of radiant energy. It also covers, but to a lesser extent, the other types of electrical apparatus found in the modern hospital. As noted in the introduction, the book attempts to bridge the gap between no knowledge of physics and advanced specialization. To the reviewer, such a bridge is too long for a single span. The major portion of the book contains material that is too far advanced for the average practitioner or student of radiology, who has no special bent for the physical problems related to his

specialty, and it is apparently designed for the person who is doing research work in this subject. The first two chapters of the book, on the other hand, deal with material encountered in the most elementary courses of science in high schools, and there is an appendix of forty pages containing the elements of algebra, trigonometry and calculus.

There is a good discussion of the methods of measurement of quantity and quality of radiant energy, but too brief a discussion of the use of metal filters. Only a part of one chapter has been devoted to discussion of the circuits commonly used in x-ray generators, and there are only a few remarks concerning the advantages and disadvantages of the various types.

On the whole, the book seems not to provide a satisfactory source of information for the average student radiology who wishes to know something of the machines with which he works.

*Blood Transfusion Association Report: Concerning a project for supplying blood plasma to England, which has been carried on jointly with the American Red Cross from August, 1940, to January, 1941.* 8°, paper, 121 pp. New York: Blood Transfusion Association, 1941.

A blood-transfusion association has been operated in New York City since 1929, with the principal object improving the supply of blood for transfusion purposes in that city. In June, 1940, in conjunction with the American Red Cross, the association greatly expanded its work to supply blood plasma for England. In a period of six months, its members collected over 5000 liters from about 15,000 persons, and much of this plasma was sent to England. After the first of January, 1941, England was able to supply its own needs, and the organization closed down this part of its work. Wisely, however, research concerning the advantages and disadvantages of blood plasma or blood serum, both in the liquid and the dried states, has been continued, and this work is to be carried on until more definite conclusions can be reached. The report of this six-month endeavor contains much valuable information about the organization of the work, and is a medical report of great value. It is a welcome addition to the literature.

*Applied Physiology.* Oxford Medical Publications. Samson Wright, M.D., F.R.C.P. Seventh edition. 10 cloth, 787 pp., with 367 illustrations and 5 color plates. New York: Oxford University Press, 1940. \$7.00.

Since the first edition of this commendable textbook published in 1926, the author has been consistent in his aim to present the facts of physiology for use by men working in the wards and various other departments of hospitals. This new edition has been drastically revised by the incorporation of recent advances in this science. As a member of the editorial staff of Section A-III of the *British Chemical and Physiological Abstracts*, the author was particularly well placed for the task.

The book has been enlarged, and contains five color plates and many illustrations. Students will find many cross references of recent investigations, inserted throughout the text. It may be noted that the author has not lost sight of the academic aspect of physiology in his emphasis on its applied aspects.

## PERICARDIOSTOMY FOR SUPPURATIVE PERICARDITIS\*

A Report Concerning Ten New Cases and Twenty-Eight Cases from the Literature

JOHN W. STRIEDER, M.D.,<sup>†</sup> AND WILLIAM R. SANDUSKY, M.D.<sup>‡</sup>

BOSTON

DURING the last half century, there have been numerous contributions to the literature dealing with suppurative pericarditis. In recent years comprehensive reviews by Shipley and Winslow,<sup>1</sup> Bisgard,<sup>2</sup> Truesdale<sup>3</sup> and others have summarized the present knowledge of the subject and have collected the recorded cases treated by pericardiostomy. Thus, up to January 1, 1934, Shipley and Winslow<sup>1</sup> were able to collect 227 cases. In this series, there were 102 deaths, a mortality of 44 per cent.

In this paper, we report 5 cases of acute suppurative pericarditis in which pericardiostomy was performed by one of us (J.W.S.), record 5 additional cases from the records of the Boston City Hospital, and review a series of 28 cases collected from the literature from January 1, 1934, to January 1, 1940. The addition of these cases from the Boston City Hospital brings the total of the recorded cases to 265. The 10 reported cases are summarized in Table I, and the 28 collected cases in Table 2.

The frequency of the disease is emphasized by Pyrah and Pain,<sup>27</sup> who found acute pericarditis in 214, or 2.7 per cent, of 7965 autopsies performed at the Leeds General Infirmary from 1921 to 1931. Of these, 91, or 1.1 per cent of all cases, were classified as acute suppurative. This figure is supported by an incidence of 177 cases, or 1.8 per cent, described as acute suppurative among 9536 autopsies performed at the Boston City Hospital from 1916 through 1938. In the same trend is a figure of 1.1 per cent of 1795 autopsies at the Massachusetts Memorial Hospitals. Stenbuck<sup>12</sup>

states that in the nine years prior to December, 1936, there were 4000 autopsies at the Mt. Sinai Hospital. In this series, there were 67 cases of acute purulent pericarditis, in which only 1 patient had been operated on. Many of the cases in this series were, of course, a single manifestation of an overwhelming sepsis and, as such, were but an incident in the progress of the fatal illness.

Notwithstanding the frequency of its occurrence, Cabot<sup>28</sup> states that 77 per cent of all cases of pericarditis, found at autopsy at the Massachusetts General Hospital were not diagnosed during the life of the patient. These figures, however, are somewhat misleading because, although these cases are termed acute pericarditis, they were not all purulent. Thus, it seems to us that cases amenable to surgery might have a higher percentage of correct diagnoses, since, as mentioned above, many cases termed acute pericarditis are incidental and, indeed, terminal.

This impression is confirmed by Bigger<sup>22</sup> in analyzing 17 cases of acute fibrinopurulent or purulent pericarditis from the Medical College of Virginia Hospitals. Seven of the frankly purulent ones were correctly diagnosed, and 6 were drained. Of the remaining 10, first diagnosed at autopsy, only 4 had a demonstrable increase in pericardial fluid, and in the other 6, death occurred from an overwhelming infection before there had been an opportunity for pus to form in the pericardial sac. All 4 of the patients who were found on post-mortem examination to have a demonstrable increase in fluid were moribund when admitted to the hospital, 3 dying in less than twelve hours and 1 in twenty-four hours.

Since the disease is never primary, except in the sense that it occurs as a complication of direct trauma (although Morin<sup>4</sup> has reported a case that

TABLE 1. Data on Reported Cases.

CASE NO.	DATE	AGE	SEX	ORGANISMS	DURATION OF ILLNESS	ANTECEDENT DISEASE	PHYSICAL SIGNS	X-RAY	TAP	TYPE OF OPERATION	DRAINAGE MATERIAL	IRRIGATION	RESULT
1	1937	48 yr.	M	Type 8 pneumococcus	4 days	Pneumonia (left lung)	Diagnostic (rub)	Diagnostic	+	Resection left 4th and 5th cartilages	None	Saline solution	Died, 10 days (septicemia)
2	1938	13	F	<i>Staph. aureus</i> (hemolytic)	12 hours	Pneumonia, septicemia	Diagnostic (rub)	Not diagnostic	+	Resection left 4th and 5th cartilages	None	Saline solution	Died, 42 hours (septicemia)
3	1939	33	M	<i>Staph. aureus</i>	4 days	Stab wound	Diagnostic (no rub)	Diagnostic	Not done	Resection left 5th and 6th cartilages	None	Dakin's solution	Recovered
4	1940	44	F	<i>Staph. albus</i>	2 days	Ulcerative colitis	Diagnostic (rub)	Not diagnostic	+	Resection left 5th and 6th cartilages	None	Dakin's solution	Died, 7 days (septicemia)
5	1940	15	M	Type 5 pneumococcus	Few hours	Lobar pneumonia (left lung)	Diagnostic (rub)	Diagnostic	No fluid obtained	Resection left 5th and 6th cartilages	None	Dakin's solution	Recovered
6	1913	30	M	Pneumococcus	Few hours	Pneumonia (right lung)	Diagnostic (rub)	Diagnostic	+	Resection right 4th and 5th cartilages	Cigarette	None	Recovered
7	1917	17	M	?	28 days	Bilateral empyema	Diagnostic (no rub)	Diagnostic	+	Resection left 5th cartilage	Rubber tissue	None	Died, 28 days (pneumonia)
8	1921	14	F	<i>Staph. aureus</i>	1 day	Septicemia	Diagnostic (no rub)	Diagnostic	+	Resection left 5th and 6th cartilages	Rubber tube and gauze	None	Died, 23 days (pulmonary edema)
9	1929	18	M	<i>Staph. aureus</i>	2 days	Broncho-pneumonia	Diagnostic (no rub)	Diagnostic	+	Resection left 6th and 7th cartilages	Rubber tube	Saline solution	Recovered
10	1930	12	M	Type 1 pneumococcus	Few hours	Lobar pneumonia and empyema (right lung)	Diagnostic (no rub)	Not diagnostic	+	Resection of one cartilage (closed drainage)	Rubber tube	Dakin's amniotic fluid	Died, 15 days

he considers primary), pericarditis may well be obscured by the original infection, particularly, as is so often true, if this infection is within the thorax. Thus, in our 10 cases, 7 were secondary to pneumonia or empyema, or both; 2 were secondary to septicemia, and 1 followed a stab wound. Twenty-seven of the 38 cases reported since 1934 followed affections of the chest, as shown in Table 3. Although it is not the purpose of this paper to go exhaustively into diagnosis, one cannot but assume, in the light of the foregoing, that an improvement in diagnosis will be obtained only if the physician, in the absence of localizing symptoms, makes careful repeated examinations of the cardiac region. Further, as Bigger<sup>23</sup> points out, if a friction rub is not heard and there is no appreciable increase in the amount of intrapericardial fluid, the diagnosis cannot be made. No rub was heard in 5 of our 10 cases. The roentgenographic and fluoroscopic findings may, therefore, be of no diagnostic aid in a certain percentage of cases, and this was true in 2 of the 10 cases that we report. Nevertheless, roentgenographic examination is of the utmost importance in diagnosis and should be carried out in the upright and prone positions, as suggested by Hodges,<sup>24</sup> so that alterations in the pericardial shadows resultant on these changes in position may be observed.

Heyl<sup>9</sup> has described fluid waves moving down the borders of the pericardial shadow, initiated by systole, that he observed fluoroscopically and that he considered pathognomonic of fluid in the pericardium. Not infrequently, the patient is too ill to permit careful fluoroscopy.

In cases of questionable diagnosis, one may have recourse to pericardicentesis or exploratory operation. Although the former procedure carries undeniable risks (we have seen unwitting puncture of an enlarged heart result in death from hemo-pericardium with cardiac tamponade), we believe it should be carried out before exploration is undertaken. It was performed without incident in 9 of our 10 cases, and, in the case in which it was not performed (Case 3), pus draining from the stab wound established the diagnosis.

On the basis of our personal experience and the recorded cases, we cannot agree with Elkin,<sup>30</sup> who believes it is safer to expose the pericardium by operation than to perform pericardicentesis. Although we agree that pericardiostomy is, itself, attended by little or no risk, we should qualify this by stating that, if fluid is not obtained by pericardicentesis after one or two attempts, further efforts should be abandoned in favor of exploration, particularly if the patient is suffering from the effects of cardiac tamponade.

It is well known that post-mortem examination of patients dying of pneumonia and its complications may reveal a varying accumulation of sterile fluid in the pericardium while there is, at the same time, actual pus in one or both pleural cavities. This has been particularly likely to occur since the advent of chemotherapy. Finland<sup>21</sup> offers the suggestion that the diffusion of the drug into the pericardial fluid suffices to kill such organisms as traverse the pleura and pericardium, whereas the initial or continuing infection of the pleura cannot be taken care of because of a low concentration of the drug, the great number and virulence of the organisms or an excessive amount of so-called "inhibiting substance" in the infected pleural cavity. All three of these factors may operate simultaneously.

This chain of circumstances, when present in a patient who has clinical evidence of acute pericarditis, may pose a nice question of judgment, and was actually encountered in 2 of our patients (Cases 5 and 9). Thus, if organisms cannot be demonstrated in the pericardial fluid obtained by pericardicentesis, and the patient has an empyema, or has had pneumonia, and is clinically suffering from the effects of pericarditis, should pericardiostomy be undertaken?

Of course, one cannot answer this question categorically. We believe that there are sound reasons for proceeding with operation in the face of this negative evidence, because of the considerable advantages to be derived from drainage before the pus becomes thick and fibrinous. We have found this to be true in 3 cases in which the patients were operated on before thick pus had formed (Cases 4, 5 and 9); all recovered. Certainly, one cannot know whether the fluid will remain sterile or become purulent, but if the patient is relieved by pericardicentesis and the fluid remains clear, one is, perhaps, justified in repeating the aspiration and observing the character of the fluid for a day or two longer.

#### TREATMENT

Although it has been stated that suppurative pericarditis, unoperated, has a mortality of 100 per cent, this is not strictly true, since cases of spontaneous evacuation, with recovery, and of recovery after repeated pericardicenteses can be found in the literature. The percentage of such cases, of course, must be extremely small, and it is to be regretted that, with the advent of the use of sulfanilamide and related compounds, probably increasing numbers of ill-advised trials of such non-operative measures will be made. It is only the occasional patient with empyema thoracis who recovers with aspiration alone or in combination

TABLE 2. *Data on Collected Cases.*

CASE No	AUTHOR	SEX	AGE yr.	PRE EXISTING DISEASE	ORGANISM	OPERATION	RESULT	COMMENT
11	Morin <sup>4</sup>	M	18	None	<i>Staphylococcus</i>	Pericardiectomy	Died, 2½ months after onset of disease	Autopsy revealed no case of infection. Authors believe this is a case of "primary pericarditis."

to be cured. Nor is there any contraindication, as in acute empyema, to early open drainage.

The contrast of results in unoperated cases with those treated by pericardiostomy demonstrates that the latter offer a 50 per cent recovery rate, on the average, in collected series of cases. This is borne out in the most recently reported collected series of 99 cases by Shipley and Winslow,<sup>1</sup> in which 49 patients recovered. In the series of 38

cases considered here, there were 20, or 53 per cent, recoveries, although in the 10 reported cases only 4 patients survived. These results should be improved in the next few years with a wider use of chemotherapy in conjunction with pericardiostomy. It is generally agreed that nonoperative measures deserve no place in the treatment of suppurative pericarditis.

In considering the problem of pericardiostomy, one has a choice of several methods of approach.

**Intercostal approach.** This has been largely abandoned because of ineffectual drainage, inability to secure dependent drainage and the impossibility of exploring or visualizing the pericardial sac.

**Trans-sternal approach.** As early as 1648, Riolaus suggested trephining the sternum as a means of draining the pericardium. Winslow and Shipley<sup>32</sup> advocated this approach, but in a later communication<sup>1</sup> inclined to resection of the costal cartilages. The disadvantage of this approach is the limited opening through the unyielding sternum, even though a portion of sternum is rongeur away.

**Approach by resection of one or more costal cartilages, usually on the left.** This approach is the one most commonly employed, and usually includes the fifth and sixth cartilages—the third to eighth cartilages have been resected. The transversus thoracis muscle fibers are divided, and the left pleural leaf is wiped lateralward, exposing the pericardium, which is incised, and the cut edges are sutured to the fascia or skin. In this method, pocketing of pus may occur posterior to the heart, or the heart itself may tend to occlude the drainage opening, however, placing the patient in the prone position may improve drainage. Occasionally, the corresponding cartilages on the right are resected. This was done in one of our cases (Case 4).

**Xiphocostal or Larrey's angle approach, with resection of the seventh cartilage.** This was later modified by Ogle and Allingham<sup>33</sup> to make their epigastric approach, in which the peritoneum is stripped from the diaphragm, and the pericardium entered dependently. This method has not been widely used, and we have had no personal experience with it, but it is said to give excellent dependent drainage, although, with the patient lying on his back, it seems to be subject, and for much the same reason, to the difficulties encountered in drainage by resection of the cartilages.

**Posterior approach.** Loucks,<sup>34</sup> Moore,<sup>8</sup> Truesdale<sup>3</sup> and Andrus<sup>35</sup> have reported favorably on this method, which is designed to drain the pericardial sac in its most dependent portion when the patient is recumbent. This approach requires traversing the left pleural cavity, and if this is not obliterated by adhesions, as it was in the cases of the operators noted above, the additional load of empyema thoracis is imposed and must be dealt with. This need not be insuperable, but the impression persists that this approach may best be used as a secondary operation, if pleural symphysis is not present.

Table 4 shows the approaches used in the 38 reported and collected cases.

There is no unanimity of opinion regarding the use of drainage material once drainage has been

established surgically. All types of materials have been used without any preponderance of evidence in favor of one or another. It is undoubtedly important that the pericardial cavity be explored with the finger at the time of operation, and at any later time that pocketing may be suspected. In 3 of our patients (Cases 3, 4 and 5), it was necessary daily to pass the finger around the heart to break up completely the fibrinous adhesions that formed regularly for the first five postoperative days. The patient was not upset by this procedure and complained of pain only when the finger pressed the pericardium anteriorly against the deep surface of the sternum. Some authors have placed Dakin's tubing or another type of tubing posterior to the heart. This has seemed to us a dangerous practice, and this impression was substantiated by an accident that occurred during the convalescence of one of our patients (Case 3). Although we have used no drainage tubing in our 5 personal cases, in Case 3 we experimented with various types of irrigating and suction tubing placed at the wound edges and not within the pericardial sac. Owing to a misunderstanding, a piece of 8-mm. red rubber tubing was placed within the pericardium, so that it was in contact with the inferior aspect of the right ventricle, and allowed to remain in place for approximately twelve hours. This resulted in a deep, eroded groove in the substance of the ventricle in contact with the tube, with ensuing brisk hemorrhage from the vessels in the eroded myocardium. It was necessary to take the patient to the operating room, and to rotate the heart outward and to the left before two silk sutures could be placed to control the bleeding. Fortunately, convalescence was uneventful thereafter.

As a result of this experience, we are more firmly than ever of the opinion that drainage or irrigating tubes, placed and fixed within the pericardium, are a definite hazard.

We are completely in accord with those who have stressed the value of frequent irrigations. We have employed gravity flow from a height of not more than 50 cm. above the pericardium, directing the fluid to the posterior portion of the sac by means of a No. 14 urethral catheter inserted at the beginning and removed at the conclusion of each irrigation. We have used a liter of Dakin's solution every three or four hours while purulent drainage continues, and have noted no such reactions as were suggested by the experimental work of Beck.<sup>36</sup> It has been used with apparently beneficial results by others,<sup>33</sup> and we have observed clearing of the pericardial infection with its use, whereas infections in other

organs have persisted and the patient has gone on to die from sepsis (Case 4).

PROGNOSIS

After studying the documented cases with respect to age of patient, sex, type of approach and postoperative care of the wound, one can determine no apparent effect of these factors on the prognosis. Although it seems reasonable to assume that those patients operated on earliest stand in the most favorable prognostic light, there is no weight of evidence to bear this out either in these 38 cases, or in those previously recorded. Shipley<sup>37</sup> states that of the 7 patients who recovered in his series, all were operated on early. On the other hand, of the 5 fatal cases only 1 was a late case.

We believe that prognosis depends on, first, the condition of the patient relative to the antecedent disease—as we have stated above, if the pericarditis is but a part of a pyemia, the outcome is usually fatal—and, secondly, the virulence of the infecting organism and, as a corollary, the resistance of the host. All the common pathogens and many of the rarer ones have been reported as the causative agent of suppurative pericarditis. Table 5 shows the organisms mentioned in the

Totals	38	20	18

38 reported and collected cases. It appears from this that the pneumococcus, with 11 recoveries and 5 deaths, is the most benign of the invaders, since, of the remainder, there were 9 recoveries and 13 deaths. These assumptions are not borne out in the literature. Undoubtedly, with the newer chemotherapy one may expect an appreciable improvement in these figures.

CASE REPORTS

AUTHORS' CASES

CASE 1. C.S., a 48-year-old man, was admitted to the Third Medical Service of the Boston City Hospital on December 27, 1936. He gave a history of pneumonia of

4 days' duration. Physical signs of consolidation of the left lower lobe were present and were confirmed by roentgenogram. On December 31, 1936, a pericardial friction rub was heard over the entire precordium. On this day, also, the patient left the hospital against advice, and was apparently comfortable for a week. However, 1 week before re-entry on January 18, 1937, he began to have cough, fever, chills, sweats and pain in the left chest.

On physical examination, the heart was enlarged to percussion. There was a pulse deficit, and the sounds were distant and muffled. Later, pulsus paradoxicus and enlargement of the neck veins were observed, and the pericardial effusion was confirmed by roentgenogram. Pericardiocentesis was performed, and 440 cc. of thick, greenish yellow pus was removed. The venous pressure prior to pericardiocentesis was 260 mm. of water, afterward, 170 mm. The patient was afforded temporary relief, and the next day 520 cc. of pus was removed from the pericardium. On the following day, he was transferred to the Second Surgical Service for pericardiostomy, which was carried out under nitrous oxide and ether anesthesia. The left 4th and 5th cartilages were resected, and the pericardium was opened. About 700 cc. of thick, yellow pus was evacuated. The pericardium was sutured to the skin, no drainage material was used. Postoperatively, the pericardial sac was irrigated with warm saline solution.

The patient showed considerable improvement, but by the 7th postoperative day an empyema was noted in the left thorax, from which a hemolytic streptococcus was cultured. Thoracentesis was performed on 4 successive days, meanwhile, the condition grew progressively worse, bronchopneumonia developed, and 10 days after operation the patient died.

CASE 2 V T, a 13-year-old girl, was admitted to the Second Medical Service of the Boston City Hospital on December 14, 1938. The patient had been well until 3 days prior to admission, when she complained of severe pain in the lumbar region and frequent urination. At the time of entry, she was febrile, flushed and dyspneic.

Roentgenograms demonstrated right lower lobe consolidation. Throat cultures showed a Type 6 pneumococcus, in addition to *Staphylococcus aureus*, and 200,000 units of Type 6 antipneumococcus serum were administered. In addition, the patient received sulfanilamide and, later, sulfapyridine. On December 18, two blood cultures, which had been taken previously, yielded *Staph aureus*. In view of this, together with the failure to respond to serum therapy, it was thought that the patient had *Staph aureus* pneumonia and septicemia. She was given 200,000 units of Lederle's antistaphylococcus serum, and there was transitory improvement. On the 8th hospital day, a pericardial friction rub developed, and extension of the pneumonic process was noted. Three days later, the area of cardiac dullness increased, and a pericardial tap yielded 4 cc. of serosanguineous material. Culture showed *Staph aureus*. The patient was transferred to the Second Surgical Service, and pericardiostomy was performed on December 26. The 4th and 5th left costal cartilages were resected, and the pericardium opened. A small amount of pus and considerable fibrin were irrigated from the pericardial cavity. The pericardium was sutured to the skin, and no drainage material was inserted into the pericardial cavity. The pericardium was irrigated with warm saline solution.

Postoperatively, the condition continued to be grave, widespread bronchopneumonia with considerable pulmonary edema developed, and the patient died 42 hours after operation.

CASE 3 W B, a 33-year-old Negro laborer, was admitted to the Third Surgical Service of the Boston City Hospital shortly after having received multiple stab wounds of the chest on January 21, 1939.

On admission, he was in mild shock, and three stab wounds were noted, one over the midsternum, one in the region of the left 10th costochondral region, and one 2.5 cm. directly below the left nipple in the 5th left intercostal space from which there was moderate bleeding. Shock was relieved by heat, position, fluids and Coramine. The patient's progress was entirely uneventful until the 3rd hospital day, when he developed acute intestinal obstruction, for which laparotomy was performed under spinal anesthesia. The obstruction was found to be due to volvulus of the proximal ileum, and was relieved. The left leaf of the diaphragm was explored for evidence of injury, but none was found. There were no subsequent abdominal symptoms.

On the 8th day following entry, the wound beneath the left nipple, which had on occasion drained a small amount of bloody material, began to drain pus, and the patient became febrile. Cardiac enlargement, noted clinically, was later confirmed by roentgenograms. On February 11, examination showed—in addition to a chest wound draining pus—distended neck veins, paradoxical pulse, cardiac enlargement and a venous pressure of 170 mm. of water. The patient was transferred to the Second Surgical Service, and on February 12, under cyclopropane anesthesia, pericardiostomy was carried out. The left 5th and 6th cartilages were resected, the pericardium was opened, and approximately 1000 cc. of foul pus was aspirated. *Staph aureus* was obtained on culture. The cavity was irrigated with physiologic saline solution, and the edges of the pericardium were sutured to the skin. No drainage material was placed in the pericardium. The patient showed immediate improvement.

The day following operation, an irrigating catheter was placed midway in the right border of the wound, but was not allowed to pass within the pericardium, the over flow was taken care of by another tube placed at the wound edge and connected to continuous suction. This system functioned well and kept the pericardial cavity bathed in fresh solution, at first, saline and, later, Dakin's solution. On February 23, the position of the catheter was changed to the lower angle of the wound and, inadvertently, allowed to remain in contact with the inferior aspect of the right ventricle for about 12 hours. The constant action of the heart against the catheter eroded the myocardium of the right ventricle. Two days later brisk hemorrhage from a myocardial vessel in the substance of the right ventricle occurred. It was discovered immediately, and two fine silk sutures were placed so as to occlude the bleeding vessel. Following this, the patient's recovery was steady, and by May 10 the pericardial wound was completely closed. However, there remained a short draining sinus down to the left 6th cartilage near the costochondral junction. Since the pericardium was well covered by skin, this sinus was excised. It filled in completely after several weeks.

Shortly before discharge, on June 26, a roentgenogram showed the size of the patient's heart to be normal. An electrocardiogram obtained in September, 1939, was well within normal limits. The patient has been followed for 20 months since operation. He is well and working as a coppermith. There is no evidence of adhesive pericarditis or impaired cardiac reserve on normal activity.

CASE 4 H S, a 44-year-old woman, had had ulcerative colitis for 10 months prior to her admission to the Boston City Hospital on June 25, 1940. There had been

a weight loss of 20 pounds. She was treated medically until August 23, when an ileostomy was performed. Following this, she had a very unsatisfactory course, since she could not be kept in fluid balance and the albumin-globulin ratio was reversed, the total serum protein being 4.5 gm. per 100 cc.; the blood chlorides remained about 85 milliequiv. per liter.

On October 2, a pericardial friction rub with pericardial effusion was noted, and at the same time there was evidence of sepsis in the right eye. Pericardicentesis was performed, and seropurulent fluid was obtained in which staphylococci were seen on direct smear. Pericardiostomy was performed on October 3, at which time her condition was poor. The 5th and 6th left costal cartilages were resected, and the pericardium was opened. Between 500 and 700 cc. of thin, yellow pus, which showed *Staph. aureus* and *Staph. albus* on culture, was evacuated.

The patient improved somewhat following this, but she continued to have frequent bowel movements. Ulcerations perforated the right cornea, and pus drained from the eyeball. She also developed a rectovaginal fistula. There was a small bloody effusion in the left pleura from which *Staph. aureus* was cultured, but which was well localized by aspirations. It was necessary daily, for the first 5 postoperative days, to break up, with the finger, fibrinous adhesions that formed between the heart and pericardium. The patient failed and died on October 11.

Autopsy revealed no infection of the pericardium. There were a localized collection of blood clots in the left costovertebral pleural gutter, panophthalmitis of the right eye and generalized peritonitis, the result of the perforation of one of the ulcerations of the ileum.

CASE 5. J. P., a 15-year-old boy, was admitted to the Fourth Medical Service of the Boston City Hospital on October 15, 1940. He was desperately ill with a left-upper-lobe pneumonia of 2 days' duration, as demonstrated by physical signs and roentgenograms. Sulfathiazole therapy was begun, and a Type 5 pneumococcus was identified in the sputum. The blood culture taken on admission was also positive for Type 5 pneumococcus. There was definite improvement, but the temperature did not return to normal after 3 days.

On October 19, a pericardial friction rub was heard, and a roentgenogram showed definite pericardial effusion and also fluid in the left pleural cavity. There was marked pulsus paradoxicus. Pericardicentesis yielded no fluid, but the picture was so characteristic and the patient's condition so precarious that exploration of the pericardium was believed to be indicated, and he was transferred to the Second Surgical Service. Under local anesthesia, the 5th and 6th left costal cartilages were resected. Before the pericardium was opened, a needle was inserted and turbid straw-colored fluid obtained, which on direct smear showed numerous polymorphonuclear leukocytes but only questionable cocci. The left pleural lappet was fused and densely adherent to the pericardium, so that it was necessary to enter the pericardium by traversing the fused pleural layers. In so doing, no air was observed to enter the pleura, but a few cubic centimeters of fluid escaped. The pericardium, which was grossly thickened, was opened widely in the usual manner, and about 300 cc. of turbid fluid aspirated.

During the ensuing 2 weeks, many repeated cultures from the pericardium yielded Type 5 pneumococcus, although the cultures taken at operation were sterile. For the first 7 days, it was necessary daily to pass the finger around the heart to break up the fibrinous adhesions

that had formed. On October 31, after several thoracenteses, a portion of the left 8th rib was resected, and the Type 5 pneumococcus empyema drained. Following this, convalescence was uneventful. The pericardiostomy wound healed in 40 days. The electrocardiogram was within normal limits, the empyema cavity obliterated, and the patient was discharged from the hospital on December 14.

#### ADDITIONAL BOSTON CITY HOSPITAL CASES\*

CASE 6. W. P. B., a 30-year-old physician, was admitted to the First Medical Service of the Boston City Hospital on January 18, 1913. He had had pneumonia 18 months previously, and at the time of admission was prostrated, dyspneic and cyanotic. On the following day, signs of consolidation in the right upper lobe were noted. After 3 days of high fever and a rather toxic course, the temperature dropped sharply to normal and the lungs cleared.

On the 5th day after entry, a pericardial friction rub was audible, and the patient was again febrile. Three days later, signs of pericardial effusion were present, and by January 31, 1913, the effusion had increased, the pulse became irregular and paradoxical, and the patient continued to be febrile. On February 18, aspiration of the pericardium yielded thick, yellow pus, from which pneumococci were cultured. On the same day, he was transferred to the Third Surgical Service, and pericardiostomy was performed under ether anesthesia by the late Dr. E. H. Nichols. The pericardium was entered after resection of segments of the right 4th and 5th costal cartilages, and 300 cc. of thick, yellow pus evacuated. A rubber-tissue cigarette drain was inserted into the pericardial cavity.

The patient was markedly improved following the operation, and his temperature at once became normal. On March 26, 1913, a portion of necrotic rib was removed, following which the wound promptly healed.

The patient at the present time (December, 1940) is in good health and actively engaged in practice as a dermatologist. There are no cardiac symptoms.

CASE 7. S. E., a 17-year-old boy, was admitted to the Second Medical Service of the Boston City Hospital on November 27, 1917. Two weeks before entry, he began to have substernal and generalized pain throughout the chest, dyspnea, orthopnea and, later, chills, fever, sweating and anorexia.

On admission, the temperature was 102°F.; the patient was acutely ill, with a flushed face, but there was no dyspnea or cyanosis. At the base of the right chest posteriorly there was dullness, the breath sounds were diminished, and a few rales were heard. The liver was not enlarged, and there was no edema. The left border of the heart was 2 cm. beyond the mid-clavicular line in the 5th interspace, and the sounds were distant. The patient continued to be quite ill, and dyspnea and cyanosis developed.

Examination on November 30 revealed fluid at both bases, further increase in the area of cardiac dullness, and distant and muffled sounds; the liver was enlarged, and there was peripheral edema. On December 3, there was roentgenographic evidence of pericardial effusion. The patient continued to run a septic course and developed an irregular paradoxical pulse, the cardiac shadow increased in size, the cyanosis, dyspnea and peripheral edema increased, and ascites developed. On December 30, pericardicentesis was done, and 550 cc. of thin, greenish pus was obtained. The next day, pericardiostomy was per-

\*We are indebted to Drs. H. A. Bouvé, E. D. Churchill and H. B. Loder for permission to report the cases of the patients on whom they operated.

formed under ether anesthesia by the late Dr E H Nichols. A portion of the sternum and the 5th left cartilage were resected, and the pericardium opened. A rubber wick was inserted for drainage, and the wound was closed about the drain.

The patient was much improved by operation, and the pericardial wound drained profusely. He did well for 8 days, and there was a decrease in the amount of drain age. The wound became a small sinus, and completely closed on the 15th postoperative day. The patient then became irrational and edematous, developed bronchopneumonia, and died on the 28th postoperative day.

CASE 8 B C, a 14-year-old girl, was admitted to the Third Medical Service of the Boston City Hospital on August 15, 1921. Two weeks before entry, she had noted swelling, heat and tenderness of the distal phalanx of the right index finger, which discharged pus spontaneously. The patient was apparently well until 8 days before entry, when the right knee joint became painful, red and swollen. On admission, she appeared quite toxic. There were redness, swelling and tenderness in the distal phalanx of the right index finger, heat and swelling over the anterior portion of the right knee and marked tenderness on motion of the knee. The day following admission under gas oxygen anesthesia, incision and drainage of the abscessed right index finger and right prepatella bursa were carried out. Cultures of the pus from each yielded *Staph aureus*.

The patient continued to run a septic course and on September 22, enlargement of the cardiac area was noted and was confirmed by roentgenogram. The sounds were muffled, the pulse paradoxical, and there were compression signs in the left lung. Cyanosis, dyspnea, precordial pain, abdominal distention and free peritoneal fluid were present. The same day, pericardicentesis yielded 360 cc of thick, grayish green pus. The patient was markedly relieved following this, and on the next day, under ether anesthesia, pericardiostomy was performed by Dr H B Loder. Segments of the left 5th and 6th costal cartilages were resected, and the pericardium was opened. A rubber tube was inserted into the pericardium.

Postoperatively, the patient failed to improve, continued a febrile course with increasing ascites, and died 23 days after operation.

CASE 9 M S, an 18-year-old student, was admitted to the Fourth Medical Service of the Boston City Hospital on December 5, 1930. One week before entry, he began to feel sharp pains in the ensiform region, made worse on breathing and accompanied by fever, headaches and anorexia. On the day before entry, the chest pain became worse, and there were dyspnea and a nonproductive cough.

On entry, the chest findings were consistent with a moderate bilateral effusion, and the heart was enlarged. Thoracentesis was done, and 100 cc of slightly cloudy, yellow fluid was removed from the left chest. Cultures showed no growth. A febrile course continued, and on the 6th day, 450 cc. of similar fluid was removed from the left chest. On the 12th day, it was noted that the area of cardiac dullness was increased, and the pulse was paradoxical. At no time was a pericardial friction rub heard. At this time, there were definite signs of fluid in the right thorax, and thoracentesis yielded 1250 cc of slightly cloudy, yellow fluid from which no organisms could be cultured. On the 19th hospital day, fluid was again removed from the right thorax, and at this time the area of cardiac dullness was very definitely increased. This was confirmed by a roentgenogram, which revealed enlargement both to the right and to the left. On Decem-

ber 24, pericardicentesis yielded 20 cc. of yellowish purulent fluid. Smear showed no organisms, and culture revealed no growth. By that time, the patient was very much worse, dyspnea, orthopnea and cyanosis were increasing. Two days later, a pericardiostomy was performed by Dr E D Churchill, under local anesthesia. Segments of the left 6th and 7th costal cartilages were resected, and a very thick, fibrous pericardium exposed and opened. A large quantity of pus was evacuated. Cultures from this yielded *Staph aureus*. A tube was inserted just within the pericardium.

The patient experienced immediate relief, and his postoperative course was uneventful. He was discharged from the hospital on the 48th postoperative day, symptom free and with the wound healed.

CASE 10 F L, a 12-year-old boy, was admitted to the Pediatric Service of the Boston City Hospital on June 8, 1930. He gave a history of malaise, fever and chills.

The entire right chest showed flatness, decreased breath sounds and decreased vocal and tactile fremitus. A roentgenogram revealed uniform density of the entire right chest, with displacement of the heart and trachea to the left. On June 10 the empyema was drained by the intercostal closed method, and 1400 cc of pus was obtained from which a Type 1 pneumococcus was cultured. Following this procedure, there was some improvement, although the patient continued to be febrile.

On June 19, physical examination showed cardiac dullness extending into the left midaxillary region. The heart sounds were faint and indistinct. A diagnosis of pericarditis was made, and pericardicentesis on June 19 yielded pus containing Type 1 pneumococcus. On the same day, pericardiostomy was performed by Dr H A Boue. Under local anesthesia, a cartilage was resected and a catheter inserted into the pericardium through a trocar.

The patient failed to improve postoperatively, and died on the 15th day following operation.

#### SUMMARY AND CONCLUSIONS

Ten cases of suppurative pericarditis treated by pericardiostomy and hitherto unreported are presented.

Twenty-eight additional cases have been collected from the literature from January 1, 1934 to January 1, 1940, which, with the above 10 cases, brings the total of recorded cases to 265.

Suppurative pericarditis is not a rare disease, as is demonstrated by the autopsy figures.

The diagnosis is frequently missed, because the condition is obscured by concomitant thoracic disease.

In untreated cases, the mortality approaches 100 per cent.

With pericardiostomy, the treatment of choice, the mortality is 50 per cent.

With chemotherapy as a supplement to pericardiostomy, there should be a further reduction of mortality.

Pericardiostomy should be undertaken early to achieve optimal surgical conditions and probable further lowering of mortality. Such a policy may involve operating on a certain number of patients in whom the diagnosis cannot be proved by peri-

cardicentesis, and even in a few in whom organisms cannot be found in the fluid obtained by early pericardicentesis.

## DYSPHAGIA AND NUTRITIONAL DEFICIENCY\*

DUDLEY MERRILL, M.D.,† AND ROBERT RICHARDS, M.D.‡

WRENTHAM, MASSACHUSETTS

THE most significant causes of dysphagia are carcinoma and other malignant tumors of the esophagus, cardiospasm or achalasia of the esophagus, benign esophageal stenosis (or stricture), hypochromic anemia, with the Plummer-Vinson syndrome, and paralysis of the ninth or tenth cranial nerves. Dysphagia very rarely occurs in association with a dilated left auricle, pericarditis, a sacular aneurysm, a dissecting aneurysm or an anomalous aortic arch.<sup>1</sup> A certain degree of dysphagia may also be present in gastric diaphragmatic hernias, especially in those cases in which there is a congenitally short esophagus or in which the lower end of the esophagus is kinked as a result of hernia.<sup>2</sup>

Since cancer of the esophagus is one of the most inexorable forms of neoplastic disease and since most of the other conditions causing dysphagia are amenable to appropriate therapy, it is imperative to establish the etiology of a given case so that the proper treatment may be promptly instituted.

Recently, several cases have come to our atten-

tion that at first were thought to be cancer of the esophagus but on further study were found to have dysphagia apparently due to polyneuritis secondary to nutritional deficiency. An adequate diet, with vitamin supplements administered by mouth, by stomach tube or by gastrostomy tube, as the situation necessitated, resulted in amelioration of the polyneuritis and disappearance of the difficulty in swallowing.

This aspect of deficiency disease has rarely been stressed in this country, but seems to be sufficiently important to warrant serious consideration.

In 1924, Vinson,<sup>3</sup> reporting 415 cases of "cardiospasm," said that the etiology is unknown but "among the causes may be primary spasm, primary atony of the musculature of the esophagus, irritative lesions of the vagus nerves [*italics ours*], esophagitis, fissures of the cardia, kinking of the esophagus at the hiatus esophagi and extrinsic pressure from the liver."

In 1938, Carr and Vinson<sup>4</sup> considered cardiospasm to be due to either vagal hypoactivity or a sympathetic hyperactivity, or both, but they admitted that the underlying cause of the autonomic imbalance is unknown.

\*From the Pondville Hospital, Massachusetts Department of Public Health.

†Senior physician and assistant internist, Pondville Hospital.

‡Formerly, resident physician, Pondville Hospital.

Knight,<sup>6</sup> studying the physiology of the esophagus in cats, concluded:

(1) The esophagus receives a sympathetic innervation (2) There is a true intrinsic sphincter at the cardia (3) Vagal stimulation causes tetanic contraction of the upper one third of the esophagus, which is composed of striated muscle. This contraction is augmented by sympathetic stimulation (4) Vagal stimulation causes increased tonus and motility of the lower one third of the esophagus, which is composed of smooth muscle. The tonus and motility are inhibited by sympathetic stimulation (5) Bilateral vagal section reproduces the appearances of achalasia of the cardia. Simultaneous removal of the sympathetic fibres prevents the onset of this obstruction. When the obstruction develops it can be relieved by section of the sympathetic supply to the sphincter (6) The sympathetic supply of the cardiac sphincter is accessible as it passed to the sphincter along the course of the coeliac axis and left gastric arteries

Pollitzer<sup>6</sup> reported a case of marked esophageal dilatation in a sixty seven year-old woman who had had dysphagia for thirty years. Autopsy showed compression of the vagus nerves by enlarged mediastinal lymph nodes. He believed that pressure on the vagus nerves had caused dilatation of the esophagus.

Various authors<sup>7-13</sup> have reported pathologic findings in Auerbach's plexus in post mortem studies of cases with achalasia of the esophagus. Constant findings were degeneration of this nerve plexus and hypertrophy of the circular muscular layer of the esophagus. Occasionally, in addition, small collections of lymphocytes and plasma cells, which suggested a certain amount of chronic inflammation, were found scattered throughout the wall of the esophagus.

Lendrum<sup>13</sup> has pointed out that the loss of ganglion cells in Auerbach's plexus is as great in the undistended portion of the lower esophagus as in the distended portion. This fact suggests that the pressure associated with the distention is not the cause of the degenerative changes in the nerve plexus.

Looser<sup>14</sup> reported a case of cardiospasm with enormous dilatation of the esophagus in a twenty-one year-old woman whose symptoms dated back to diphtheria at the age of twelve. He mentions no paralysis in this case, and he effected a cure by forcible dilatation of the lower end of the esophagus after performing a gastrostomy.

In view of the present day knowledge of the significance of nutritional deficiency in the etiology of many types of polyneuritis, it is of great interest that Vinson,<sup>15</sup> reporting 186 cases of cicatricial (benign) stricture of the esophagus in 1927, noted the following etiologic factors: 18 cases had no obvious cause for stricture, 14 fol-

lowed typhoid fever, 13 followed severe vomiting of pregnancy, and the remaining 141 were accounted for by various caustics, congenital defects and infectious diseases. In other words, 27 cases out of 186 (14 per cent) developed following typhoid fever or pernicious vomiting of pregnancy, conditions that are now known to be frequently associated with manifestations of deficiency disease. Vinson does not, however, include sufficient clinical information to enable one to estimate the incidence of recognizable deficiency-disease syndromes among his patients.

Turner,<sup>16</sup> reporting on 19 cases of nonmalignant esophageal stenosis, found that 5 were due to ingestion of corrosives, 5 were congenital, 4 were due to acute inflammation, and in 2 the cause was undetermined. He also said that simple strictures have followed scarlet fever, typhoid fever and the vomiting of pregnancy, but offered no explanation of this unusual sequence of events.

Stinson,<sup>17</sup> in 1938, reported 4 cases treated and cured with thiamin chloride. He came to the conclusion that cardiospasm is a manifestation of vitamin B<sub>1</sub> deficiency, that vitamin B<sub>1</sub> given intramuscularly relieves certain types of cardiospasm, and that the continued administration of this vitamin prevents the recurrence of attacks. Unfortunately, his paper includes no histories of dietary deficiency, nor does he include descriptions of physical signs of the better known syndromes now accepted as being due to vitamin deficiency. From the evidence given, it is hardly justifiable to consider that he has proved the etiologic relation of vitamin B<sub>1</sub> deficiency to cardiospasm.

Meiklejohn<sup>18</sup> has recently cast some doubt on the experimental evidence usually quoted as proving that thiamin (vitamin B<sub>1</sub>) is actually the antineuritic vitamin, but he concedes the relation of dietary deficiency to certain neuritides.

Fenwick,<sup>19</sup> in 1893, published a paper discussing spasmodic stricture of the cardiac orifice of the stomach. He noted "Habitual drunkards are very liable to the complaint especially after indulgence in an unusually deep debauch. In many of these cases a bougie is only arrested in the immediate neighborhood of the stomach, but in others the obstruction is encountered just below the pharynx." He mentions one case in a youth with acute phthisis, and also says that dysphagia sometimes appears following an acute febrile illness. Of some historical interest is his comment that a mild form of the complaint is frequently encountered in emotional and anemic women between the ages of eighteen and thirty, in some cases making its appearance coincident with the establishment of the menses. Perhaps he refers here to two

conditions that would now be diagnosed as globus hystericus and idiopathic hypochromic anemia with the Plummer-Vinson syndrome.

Jankelson<sup>20</sup> reported 6 cases of dysphagia that were relieved by the administration of vitamin B. One of his patients had severe polyneuritis, another had paresthesias and weakness of the arms, and a third had pain in the calf muscles and marked general weakness. The others had no demonstrable neuritis. Four patients had no x-ray evidence of disease in the esophagus or stomach, one had a small diverticulum in the middle third of the esophagus, and the sixth case had no x-ray studies reported.

Manson-Bahr,<sup>21</sup> in discussing the nerve lesions of beriberi, says that the cranial nerves above the seventh are rarely involved, but in some cases the laryngeal muscles are paralyzed. In the infantile form of beriberi, laryngeal paralysis is believed to be relatively common, and dysphagia and aphonia may be present.

Vedder,<sup>22</sup> discussing the pathology of beriberi, states that degenerative changes are found in the posterior columns as well as in the anterior and posterior nerve roots and ganglion cells. He adds, "It is especially to be noted that degeneration of the sympathetic system has been demonstrated, as in branches of the cardiac plexus, the splanchnic nerves and branches of the solar and renal plexus."

Laryngeal symptoms have been reported in beriberi by Fernando,<sup>23</sup> and paralysis of both recurrent laryngeal nerves in beriberi by Miura.<sup>24</sup>

Etzel<sup>25</sup> and Netto<sup>26</sup> believe that achalasia of the pylorus in the adult is identical in etiology and pathologic physiology with megaesophagus (achalasia of the esophagus), hypertrophic pyloric stenosis in the newborn, and megacolon, these conditions being due to vitamin B<sub>1</sub> deficiency. The pathology in all is the same and consists in marked diminution of elements of Auerbach's plexus.

Brodie,<sup>27</sup> in some experimental work on rats on the etiology of congenital pyloric obstruction, was able to produce this condition in 10 out of 23 young rats (four litters) by keeping the mother's diet minimal in antineuritic vitamin (B complex). The vagus nerves of the affected rats showed myelin degeneration.

The preceding observations suggest that dietary deficiency may be a cause of dysphagia, although the mechanisms involved may vary.

Iron-deficiency anemia associated with dysphagia causing the Plummer-Vinson syndrome has been so frequently reported that no further mention of it will be made here, even though the mechanism

by which the dysphagia is brought about is anything but clear.

The following 3 cases are reported as examples of dysphagia secondary to nutritional deficiency.

### CASE REPORTS

CASE 1 (formerly reported by one of us [D.M.<sup>28</sup>]). R. W. (P. 7094), a 55-year-old laborer, was transferred from a large teaching hospital with a diagnosis of carcinoma of the esophagus. Two and a half months before admission, he developed a rapidly progressive dysphagia and became barely able to swallow liquids. During the same period, he lost weight and developed a generalized weakness of all the muscles, particularly of the hands and feet, associated with tingling and numbness during the last 4 weeks. He had been studied in the neurologic division of the other hospital, and diagnoses of cancer of the esophagus (on the basis of fluoroscopic examination), toxic paralysis of the 10th cranial nerves, and toxic myelitis had been made. The diagnosis of 10th-nerve paralysis was based on hoarseness, regurgitation of fluids through the nose and weakness of the left side of the palate.

The past history included exposure to tuberculosis 5 years before admission. The patient had worked for many years handling bags of lime in a very dusty atmosphere. For 5 years, he had had a "cigarette cough." He had been a heavy drinker of alcoholic beverages since the age of 14.

On examination, the positive findings were dullness, increased tactile fremitus and fine crackling rales over the right chest posteriorly. There was generalized atony and wasting of the large calf and thigh muscles and intrinsic muscles of the hands. The deep tendon reflexes were absent, the abdominal and cremasteric reflexes barely perceptible. There was slight diminution of vibration perception over both legs below the knees, and moderate tenderness to pressure along the deep nerve trunks in the thighs, calves and arms. There was a definite tendency to bilateral foot drop.

The significant laboratory findings were a red-cell count of 2,730,000 with a hemoglobin of 56 per cent (Sahli), and a white-cell count of 11,500 with a normal differential.

X-ray examination of the chest showed dullness of the upper half of the left lung and upper third of the right lung, which was interpreted as being due to tuberculosis or to metastatic carcinoma. Fluoroscopy of the esophagus showed a deformity of the first portion, without marked obstruction, and was thought to represent a large tumor projecting into the lumen of the pharynx. Studies repeated 2 weeks later showed no change. Laryngoscopy under general anesthesia showed a markedly thickened fold of mucous membrane that had the appearance of a web just behind the larynx. No ulceration was seen, and a No. 18 bougie passed readily through the esophagus.

Because of the evidence of polyneuritis and a history of alcoholism, the patient was started on a high-vitamin diet, with liver extract intramuscularly as a source of vitamin B. Although bedridden for 3 weeks after admission, he improved steadily so that he was able to stand and walk a little by the end of the 4th week. Then, because he was much stronger, esophagoscopy was performed but no disease was found; this was repeated and again was negative. It was also noted at this time that the patient could swallow even solid foods without difficulty.

Six weeks after admission, another x ray film of the chest was taken. The entire right lung was clear, only a few increased markings persisting at the left apex. The blood showed only slight improvement, in spite of liver and iron therapy. The red-cell count rose to slightly over 3,000,000, and the hemoglobin to 65 per cent.

During the 8th week, the patient developed an acute respiratory infection, with signs of congestion in both lungs. He became unco-operative, drowsy and confused. Neurologic examination and lumbar puncture were negative except for absent tendon reflexes, which had never returned. The course was then rapidly downhill. The patient developed what was thought to be a bronchopneumonia and died 12 weeks after admission.

A postmortem examination revealed multiple abscesses in both lungs, terminal bronchopneumonia, a normal esophagus and a cystic tumor of the right frontal lobe which on microscopic examination proved to be a fibrillary astrocytoma.

It is interesting that normal esophageal function as demonstrated by x ray and esophagoscopy returned while the patient was receiving large amounts of vitamin B complex, although he was suffering from a brain tumor and multiple lung abscesses that eventually caused his death.

CASE 2 E A (P 16023), a 66-year-old man, was admitted because of progressive dysphagia of 3 weeks duration. He had been an inmate of a state institution for 4½ years, with a diagnosis of manic-depressive psychosis. The throat trouble began as a sore throat, but difficulty in swallowing soon progressed to the point where even fluids were regurgitated through the nose. The patient had lost 20 pounds in the previous 2 months.

Physical examination was essentially negative except for dental caries and external hemorrhoids. Nutrition appeared to be excellent.

Because the patient was totally unable to swallow a gastrostomy was performed. Postoperatively, he did extremely well and gained weight rapidly. However, about 1 month after operation he complained of tingling of his hands and feet, his gait was unsteady, and he lost all position sense in his legs. His tongue was noted to be atrophic. Esophagoscopy revealed only a slight constriction about 25 cm from the teeth, with no evidence of cancer, although a barium swallow was promptly regurgitated and spilled into the trachea.

On gastrostomy feedings with added liver, sensation in the extremities returned, the gait became normal, and the patient was able to swallow liquids without difficulty. He was discharged back to the state institution 2 months after operation, with a diagnosis of esophageal spasm and stricture. He returned to the Out Patient Department 5 weeks later for a check up examination, at which time he was able to swallow solid foods without any trouble. The tongue was normal, but the knee jerks and biceps reflexes were absent. There was also a fine scaling desquamation of the extensor surface of the shins and forearms. A diagnosis of vitamin B deficiency, with polyneuritis and paralysis of the 10th nerve, was made, and brewer's yeast (four 7½ gr tablets after each meal and at bedtime) was prescribed.

The patient was seen again 1 month later, at which time he had gained 11 pounds and was able to eat any thing without difficulty, there was marked improvement of the paresthesia of his hands and feet. As he described it, he was able to wind his watch and know what he was doing. All evidence of dermatitis had disappeared, and the deep tendon reflexes, although sluggish, were present.

Esophagoscopy was repeated, and since no lesion was found, the gastrostomy was allowed to close.

The patient was last seen 7 months later, 11 months after the gastrostomy had been performed, he had gained another 4 pounds and had no symptoms or signs of any residual neuritis, and no symptoms referable to his esophagus.

In retrospect, it seems likely that the extensive neuritis and loss of 20 pounds of weight had been caused by the patient's failure to eat adequately during a depressed phase of his manic-depressive psychosis.

CASE 3 J W (P 10181), a 48-year-old man, was first seen in December, 1935, because of hoarseness of 4 months' duration, gnawing epigastric distress, increasing weakness and tingling, and numbness and coldness of the arms and legs. He had been able to take only milk and coffee and had had marked anorexia for the same length of time. He admitted excessive indulgence in alcohol for many years. Thirty-three years prior to admission, he had had an operation on his stomach, and 28 years later he had had an operation for ulcer of the stomach.

The striking findings on examination were marked hoarseness and inability to stand or walk without assistance. Neurologic examination showed hyperactive but equal knee and ankle jerks, and marked muscular weakness, efforts made to stand up resulted in clonic contractions of the leg muscles.

Laryngoscopy showed the vocal cords to be a little sluggish in motion, and there was a small tumor at the base of the epiglottis. A biopsy of this tumor showed only chronic inflammation.

The patient was placed on a high vitamin diet, with marked improvement of the neuritis. His appetite was excellent, he was able to swallow without difficulty, his hoarseness disappeared, and he was able to walk without support, though unsteadily, when he was discharged 1 month after admission. The final diagnosis was polyneuritis due to nutritional deficiency secondary to chronic alcoholism.

The patient was next seen again about 1½ years later, when he came to the Out Patient Department because of pain in the hypopharynx, difficulty in swallowing and hoarseness. Laryngoscopy showed marked congestion of the entire hypopharynx but no cancer. In December, 1939, after an interval of almost 2½ years, the patient was admitted from a state prison because of constant burning pain in the epigastrium, pain in the left lower quadrant of the abdomen and burning pain in the suprasternal notch. For the previous 2 years, he had been unable to eat anything except liquids and soft foods. For 14 months, he was at a veterans' hospital, where in June, 1939, because of inability to swallow, a gastrostomy had been performed. Although the gastrostomy had closed over, the patient had apparently gained 33 pounds in 6 months and could swallow better than before the operation. For the previous 12 months, he had been receiving hypodermic medication at 4-hour intervals because of abdominal pain. He had been in bed practically the entire time because of weakness. He could not lie flat in bed, however, because his throat filled up with mucus when he did.

Physical examination was surprisingly negative, considering the dramatic history. The liver edge was palpable 3 fingerbreadths below the costal margin. There were coarse tremors of the tongue and of all extremities. The knee and ankle jerks were equal and hyperactive. Gastrointestinal studies, including a barium meal and enema, were negative for any evidence of neoplastic disease. The blood Hinton reaction was negative. On a

high-vitamin diet containing brewer's yeast (six 5-gr. tablets after each meal and at bedtime), the patient improved rapidly, and was soon able to sit up and to walk when supported. He gained another 6 pounds in the 3 weeks at the hospital, and was discharged with no difficulty in swallowing and complete relief of the burning in the suprasternal notch, epigastric discomfort and left lower-quadrant pain. His strength was returning rapidly, but he still had marked muscular inco-ordination in his legs.

The discharge diagnosis was the same as that on the first admission to the hospital: polyneuritis due to nutritional deficiency secondary to chronic alcoholism. The dysphagia and aphonia were apparently due to involvement of the 9th and 10th cranial nerves by the polyneuritis.

### CONCLUSIONS

Dysphagia is occasionally a result of neuritis involving the ninth or tenth cranial nerves, which in turn is produced by nutritional deficiency, particularly of the vitamin B complex.

## LEFT-SIDED PAIN IN BILIARY-TRACT DISEASE\*

JACOB FINE, M.D.,† AND ARNOLD STARR, M.D.‡

BOSTON

THE pain of biliary-tract disease is primarily epigastric or right-sided. Occasionally, however, there is a left-sided component in the pattern of pain reference. When this happens, either pancreatitis or an extension of the pericholecystic inflammation to the left side is generally a sufficient cause. However, pain only on the left side may occur in biliary-tract disease in the absence of an inflammatory process. In such cases, which are rare, the origin of the pain in the biliary tract may be overlooked because of the clinical habit of regarding the latter as possessing an exclusively right-sided innervation. On embryologic grounds, the common duct must be assumed to have a bilateral innervation. This provides a reasonable explanation for some cases of bilateral pain in noninflammatory disturbances of the biliary ducts and for the occasional case in which there is an exclusively

left-sided reference. This is not a new observation, but two striking clinical illustrations are recorded herewith to emphasize it and thus to minimize the likelihood of a misinterpretation of the existing disease in similar cases.

### CASE REPORTS

CASE 1. A 45-year-old woman was admitted with a history of severe stabbing pain of 8 years' duration, starting in the epigastrium and radiating around the left costal margin and to the left scapula. During the more intense seizures, pain was also felt in the left shoulder and arm, spreading to the finger tips. The onset of attacks bore no relation to the ingestion of food, to the kind of food, to bowel, bladder or catamenial functions, to rest or to exercise. The pain, instead of immobilizing her, caused her to roll about in bed; it was not colicky, but rather constant, lasting from 30 minutes to 12 hours. It was not relieved by food or alkalis. There was no nausea or vomiting. Six years before entry, following an attack in which slight jaundice was noted, a cholecystectomy was performed in another hospital. The gall bladder contained numerous stones and gravel. The surgeon's note was as follows: "A moderately thickened and enlarged gall bladder was adherent to the whole length of the

\*From the Department of Surgery, Beth Israel Hospital.

‡Junior visiting surgeon, Beth Israel Hospital, instructor in surgery, Tufts College Medical School.

duodenum. The common-duct and cystic-duct regions were explored and examined. The gall bladder was removed. The common duct was negative and was not drained. The pancreas was normal.<sup>11</sup> Following operation, the patient had attacks of acute pain in the chest, which were diagnosed as angina or pseudo-angina by a consultant. When last seen by him 1 year after the operation, she was still having severe attacks of pain, cutting off her breath,<sup>12</sup> and the consultant was not certain what the diagnosis was.

The patient was admitted to this clinic 6 years after the cholecystectomy. She stated that 10 days after the cholecystectomy she had an attack of pain exactly like those preceding the operation. The attacks continued as frequently and as severely as ever, but during the previous few years there had been no radiation of pain to the left scapula and left upper extremity. The pain began just below the xiphoid process, radiated along the left costal margin and caused difficulty in breathing. Following the seizures, she felt a girdlelike, squeezing sensation, which slowly subsided. There was no nausea or vomiting and no other symptoms referable to the gastrointestinal system. No jaundice was noted at any time. Amyl nitrate occasionally relieved the pain, often it did not. Between attacks there was no intolerance of food, heartburn, flatulence or constipation, the appetite was normal. There had been an attack of pain almost daily for the 2 weeks preceding admission.

Physical examination on admission was not remarkable except for the scar of the incision in the right upper quadrant and another of an appendectomy done when the patient was 16.

The stools, blood and urine showed normal findings. The icteric index was 6, and the blood Hinton and Kahn reactions were negative. Gastric analysis gave normal findings, the spinal fluid and the sugar tolerance curve were normal, and the electrocardiogram was negative. Radiologic study of the genitourinary tract, chest, spine, stomach and intestine gave findings within normal limits. Duodenal intubation yielded crystals of calcium bilirubinate and others suggestive of cholesterol. Accordingly, the patient was explored, with a preoperative diagnosis of cholelithiasis. After old adhesions in the region of the gall bladder bed had been freed, the common duct, which was slightly dilated and thickened, was opened and a single pea-sized gallstone found and removed from the lower end.

The patient recovered uneventfully and has been entirely symptom free, enjoying excellent health ever since, a postoperative interval of 2 years.

**Comment.** The exclusively left-sided radiation of pain, in the absence of jaundice, nausea, vomiting or other symptoms that might have suggested a diagnosis of cholelithiasis, was so misleading that no physician suggested the possibility of residual stone in the biliary tract until after 6 years of continued disability.

**Case 2.** A 71-year-old woman entered the hospital because of pain, colicky in nature, radiating around both costal margins and to the interscapular area in the back. A week before entry, she experienced her first attack, in which the pain was in the right upper quadrant and radiated to the back between the scapulas. In the second attack, lasting 9 hours, which occurred on the day of admission, the pain was more pronounced on the left side, but it radiated to both sides, giving her the feeling of a rope being tied around the waist.<sup>13</sup> She found no relief in any position. There was some nausea, but no vomiting. There was no history of chills, fever or jaundice. The patient had been treated for 2 years for attacks of sub-

sternal distress, pain in the left shoulder and dyspnea on exertion. These were attributed to coronary heart disease.

On admission, physical examination revealed tenderness and spasm in the right upper quadrant of the abdomen. The electrocardiogram showed sinoauricular bradycardia (rate, 55), left axis deviation, widened QRS complexes and probable intraventricular block. The urine contained a few red and white cells per high power field, and the blood white cell count was 8900. The icteric index was 15. A Graham test showed cholelithiasis.

For 6 days preceding operation, the patient had nightly seizures of bilateral girdle pain, of equal intensity on both sides. Cholecystectomy and common duct exploration were then performed. A small gall bladder containing numerous stones was excised, and several stones were removed from a dilated and thickened common duct. Tube common-duct drainage was established. There was no pancreatitis or evidence of an acute inflammatory process in the upper abdomen.

The convalescence was smooth until the 8th postoperative day, when clamping of the T tube caused severe discomfort, which was quickly relieved by unclamping the tube. Two days later a cholangiogram showed a residual common duct stone. In view of the patient's age and cardiac condition, further surgery was deferred. She was discharged with the T tube in place.

When seen 7 weeks later, she looked well. She stated that about 100 cc of bile came out of the tube in each 24 hours. She had been entirely free of all symptoms including the precordial pain attributed preoperatively to the coronary heart disease, although she acknowledged that exertion, the usual preoperative cause of the pain, had been avoided. Before operation, however, there had been some spontaneous pain in the left chest, which had not recurred since. To establish a possible relation between the common duct stone and the left-sided pain of which she complained in the immediate preoperative period, 30 cc. of physiologic saline solution was injected slowly into the T tube. She complained immediately of pain along the left costal margin and pain in the back below the angle of the left scapula. This procedure was repeated using 45 cc of saline injected rapidly, with the reproduction of the same pain in the same area. There was no pain reference whatever to the epigastrium or to the right side. The saline solution in both instances did not return to the through tube and therefore presumably passed by the stone and entered the duodenum. Incidentally, this procedure succeeded in forcing the stone into the duodenum, since a subsequent cholangiogram showed no stone. The tube was removed, and the patient has remained well to date.

**Comment.** This is a clinical experience demonstrating beyond doubt that distention of the common duct can cause exclusively left-sided pain. It behooves the physician not to dismiss the common duct from consideration in the differential diagnosis when the presenting symptom is pain in the left upper quadrant.

### SUMMARY AND CONCLUSIONS

In two patients with stone in the common duct, pain was referred only to the left side in one and to both sides with equal intensity in the other. In the latter case, distention of the common duct postoperatively produced pain on the left side only.

Common-duct obstruction, therefore, may cause pain referred only to the left side and in the ab-

sence of other signs or symptoms suggesting disease in the biliary tract. It is not always necessary to assume the presence of pancreatitis or some

other inflammatory process spreading to the left of the mid-line to explain left-sided pain in disease of the biliary system.

## ANTHRAX\*

### Report of a Case Treated With Antiserum and Sulfathiazole

R. WILLIAM PROVENZANO, M.D.,† GEORGE E. CARRIEL, M.D.,‡ AND ARLENE BLOOMER, B.S.§

LOWELL, MASSACHUSETTS

ALTHOUGH satisfactory progress has been made in the treatment of anthrax, this disease continues to be a serious industrial hazard. The greatest number of cases occurs among tannery workers, but those among wool handlers and agricultural workers are not far behind. Although the fatalities are lessening in a few states,<sup>1</sup> the general mortality shows no tendency to decline, in spite of the fact that effective treatment is available.

Anthrax has been known since ancient times, mention being made in the Bible and by authors such as Homer, Seneca and Ovid. Although the descriptions reveal that even at that time the transmissibility of the disease to man by the fur and wool of diseased animals was known, it was not until 1823 that Barthelemy proved its contagious character in animals.<sup>2</sup> Pollender, in 1849, was the first to observe organisms in the blood of animals with anthrax.<sup>3</sup> In 1850, Davaine and Rambert demonstrated experimentally the relation of anthrax to the malignant pustule.<sup>3,4</sup> This work was confirmed by Koch in 1876 and Pasteur in 1877.<sup>3,4</sup> It was with the aid of the new methods devised by Koch that a firm foundation was laid for further investigation of the etiology and spread of anthrax.

Anthrax is a specific, virulent, infectious disease, caused by the *Bacillus anthracis* and occurring in man in three forms<sup>2,5-7</sup>: the cutaneous, the pulmonary and the intestinal. The disease is communicable to man by contact, inhalation or ingestion of material infected with anthrax. The cutaneous form, also known as "external anthrax," is further subdivided into the malignant-pustule type and malignant anthrax edema. The intestinal and pulmonary types are also called "internal anthrax."

By far the commonest type is the cutaneous infection, usually occurring as the malignant pustule.

The typical malignant pustule is a single lesion beginning with intense itching at the point of inoculation, or a burning sensation followed by the appearance of a small red papule, which within twelve or fifteen hours becomes vesicular, the vesicle showing a central depression containing brownish fluid and surrounded by a slight edematous areola. The vesicle then dries, leaving a dark-brown eschar surrounded by a number of minute silvery vesicles. The tissue about the site of inoculation becomes swollen, owing to anthracomucin, and consists of a doughy, indurated, pinkish, edematous mass. The surrounding lymph nodes are generally swollen, painful and covered by edematous skin. It should be noted that a characteristic feature of the pustule itself is the absence of pain in and about the lesion. Even when the lesion is extensive, the patient may complain of only a sense of weight and slight tenderness on pressure, or a feeling of tightness because of swelling. The surrounding vesicles then become filled with hemorrhagic fluid, and the edematous area is infiltrated with blood and sometimes undergoes gangrenous degeneration. If the infection becomes generalized, all the symptoms of collapse eventually set in, the patient becomes pulseless, and respiration ceases.

Internal anthrax occurs far less commonly, intestinal anthrax being the rarest form. The pulmonary type is brought about by the inhalation of dust impregnated with anthrax bacilli, and is usually seen in woolsorters; there are pain in the chest, cough, expectoration of bloody sputum, and cyanosis. The intestinal type is usually produced by the ingestion of spores, and the symptoms of the disease are referable to the pulmonary and intestinal tracts. In the intestinal form, there are abdominal pain, nausea and vomiting and diarrhea. The constitutional symptoms of internal anthrax are severer than those in the simple malignant-pustule form.

The diagnosis of anthrax can be made only after all the criteria have been considered. A history

§Laboratory technician, St. Joseph's Hospital.

of exposure to infection, followed by a physical examination presenting the clinical picture of anthrax, does not relieve the physician from performing bacteriologic tests that confirm the diagnosis. One must make a direct examination of the pustular secretion in the malignant-pustule form, of the sputum in pulmonary anthrax and of the feces in intestinal anthrax. Furthermore, only a positive stained smear is decisive. If the direct examination is negative, a culture should be made or a guinea pig should be inoculated before making a diagnosis including or excluding anthrax.

When the diagnosis of malignant pustule has been made, the question of therapy arises. It has been shown by recent experience<sup>8-10</sup> that any form of operation or cauterization is to be avoided, for such procedures permit the entrance of infectious material into the general circulation because of the severance of blood vessels and lymph channels, thus precipitating septicemia. It is known that the pustule of cutaneous anthrax often heals completely if no local interference is offered, and Didié<sup>11</sup> reports good results from the use of small doses of x-ray.

The accepted local treatment consists in thorough cleansing of the lesion with physiologic saline solution, absolute rest and immobilization of the affected part and the injection of antianthrax serum subcutaneously at four points fairly equidistant from the lesion, as advocated by Symmers<sup>12</sup> and by Regan.<sup>13</sup> These injections form an isolating barrier against anthrax bacilli, and should be repeated at intervals of four or six hours until the lesion is free of bacilli. The amount of serum to be used depends on the severity of the local inflammation. The lesion should then be covered by sterile gauze. Every cutaneous anthrax lesion is to be regarded as a potential generalized infection, and an intravenous injection of 150 to 200 cc. of antianthrax serum should be given, due care being taken that the patient is not sensitive to the serum. If the blood culture is found to be negative, no further intravenous injections are necessary. If one errs, it is thus on the side of safety, for valuable time is saved in the event of septicemia.

For the treatment of cutaneous anthrax with septicemia, in addition to local therapy, as described above, repeated intravenous injections of antianthrax serum are recommended. Favorable results have been reported from the use of relatively small doses of serum; however, as stated by Symmers<sup>12</sup>: "... it would appear that to depend upon the lesser quantities as a routine measure is sooner or later to court disaster—and in

dealing with a disease so treacherous as anthrax, it is well to leave a wide margin of safety." A proved, efficient therapeutic method for treatment consists in the immediate administration of 200 cc. of serum, repeating this in four hours, and then giving 50 cc. every four hours until the blood culture is negative. Nilsson<sup>14</sup> noted no difference in the therapeutic value of serum manufactured for human use and veterinary serum. Because of favorable results obtained by the use of organic arsenicals,<sup>15, 16</sup> these drugs may be employed as adjuvants to serum or as the main therapeutic agent if serum is not obtainable. The organic arsenicals, if used, should be given in one or two large doses. Small doses do not appear to have sufficient therapeutic effect to justify their use, and their cumulative effect is probably as dangerous as that of one or two large doses.

#### CASE REPORT

A 40-year-old man was admitted to St. Joseph's Hospital on September 7, 1940, with an anthrax pustule on the flexor surface of the left forearm at the level of the junction between the middle and the distal thirds of the radius. A dark-brown eschar, measuring about 2.5 cm. in diameter, was surrounded by a number of vesicles filled with hemorrhagic fluid. About 3 cm. from the eschar were two bullae filled with a brown serous fluid. The skin from the level of the middle part of the humerus to the fingers was markedly edematous, indurated, doughy and pink. The tissue in the edematous area revealed discrete pinpoint areas of hemorrhagic infiltration. Except at the time of injury, there was no complaint of pain, although the patient noted a feeling of pressure and numbness. The infected arm was about twice the size of the right arm. The axillary nodes were tremendously enlarged. The temperature was 100.2°F., the pulse 92, and the respirations 24; the white-cell count was 20,400.

The patient stated that 9 days before admission, while handling wool, he stuck a burr into the anterior surface of the left forearm. Except for slight itching in the inoculated area, there was no disturbance. The following day, he noticed a "burning sensation" and the appearance of an "area of redness." On the same day, a "pimple" developed, from which he squeezed pus. On the 3rd day, the surrounding skin began to "swell, and became hard and stiff." The swelling continued, and the hand and arm became so large that the patient sought medical advice.

At the time of admission, stained smears from the contents of the pustule and vesicles showed staphylococci but no evidence of anthrax bacilli. Agar plates inoculated directly from the pustule revealed staphylococci. A blood culture showed growth, and stained smears revealed gram-positive bacilli having the characteristic appearance of anthrax bacilli. Stained smears were again made from the contents of the vesicles; they showed anthrax bacilli. An emulsion was made, using one of the colonies on a blood-agar plate. Twenty-nine hours after the injection of 0.5 cc. of the preparation into the subcutaneous tissue of the abdominal wall of a guinea pig, the animal died. Necropsy showed a gelatinous infiltration of the superficial structures of the abdominal wall. The liver and spleen were markedly enlarged and congested. The suprarenal glands consisted of two large hemorrhagic cysts.

The kidneys showed pinpoint hemorrhagic areas. A stained smear of the free peritoneal fluid revealed the presence of anthrax bacilli, as did smears from the liver, spleen and suprarenal glands. Anthrax bacilli were grown in pure culture from the heart's blood and the suprarenal glands.

The patient was put to bed with the arm at absolute rest and in an elevated position. Staphylococci having been reported on the smears and culture, 2 gm. of sulfathiazole was administered at once. This amount was repeated in 4 hours, and then 1 gm. every 4 hours was given. Twenty-four hours later, when the blood culture revealed anthrax bacilli, antianthrax serum was administered; 150 cc. of serum was injected intravenously, and 50 cc. was injected subcutaneously at several points about the lesion. Six hours later, 200 cc. of serum was given intravenously, and 50 cc. was injected deep into the muscular tissue in the upper arm at the level of the upper and middle thirds of the humerus and again around the lesion. Six hours later, another 200 cc. of serum was injected intravenously. The amount was then cut to 100 cc. intravenously and 50 cc. about the lesion, given at 6-hour intervals. A total of 850 cc. of serum was administered in a period of 18 hours. Blood cultures taken the following morning, 17 hours after the beginning of antianthrax serum therapy, revealed the presence of anthrax bacilli. Twenty-four hours later, cultures and smears were reported negative for bacilli. Thus, after 14 days of illness, 24 hours of antianthrax serum and sulfathiazole therapy produced negative smears and cultures. Pending the report of another blood culture, 100 cc. of serum was given every 8 hours. Blood cultures and smears from the site of inoculation continued to be negative. Serum was omitted, but sulfathiazole was continued until September 16. The sulfathiazole level on September 15 was 5.1 mg. per 100 cc. A total of 1150 cc. of serum was given.

During the illness, the temperature varied from 98 to 102°F. The white-cell count fluctuated between 20,300 and 10,400. The blood smears and blood chemical findings were not remarkable. It is to be noted that 12 hours after the deep intramuscular circular injection of serum in the upper arm, a linear demarcated area of pinpoint hemorrhages was seen. Neither swelling nor dermal changes occurred above the injected area. Except for slight serum sickness, which was controlled by calcium gluconate and epinephrine in oil, the patient made an uneventful recovery and was discharged cured.

This case demonstrates the beneficial effects of massive doses of antianthrax serum. However, since staphylococci were found on smears and in cultures, sulfathiazole was administered. In view of the facts that the most beneficial effects are

obtained when antianthrax serum is used early, that late administration, even in massive doses, shows discouraging results and that, in this case, the serum was given effectively late in the course of the disease, the question is, Does sulfathiazole act synergistically with serum? In-vitro experiments performed on six different occasions showed that anthrax bacilli grew less readily on plates containing sulfathiazole powder and antianthrax serum than they did on plates containing sulfathiazole or serum alone. Although these experiments do not prove conclusively that sulfathiazole is an effective adjuvant, the results serve as a basis for further experiment.

### SUMMARY

The modern diagnosis and treatment of anthrax are discussed.

A case successfully treated with antianthrax serum and sulfathiazole is reported, and the possible value of the latter as an effective therapeutic adjuvant is considered.

## MEDICAL PROGRESS

## THORACIC SURGERY

EDWARD D. CHURCHILL, M.D.\*

BOSTON

## BRONCHIAL ADENOMA

IN last year's review,<sup>1</sup> attention was called to the discrepancies that may occur in end-result statistics purporting to deal with primary bronchogenic carcinoma by different interpretations of the nature of the so-called "bronchial adenoma." There are now sufficient definitive characteristics on record to permit the recognition of this tumor both clinically and pathologically in nearly every case. Only occasionally is the small fragment of tissue obtained by bronchoscopic biopsy inadequate for an unmistakable histologic diagnosis. If certain controversial aspects of these tumors are avoided, there seems to be general agreement on the following characteristics:

*Slow rate of growth.* Not infrequently, there is direct proof from symptoms, radiography or bronchoscopic biopsy that the tumor has been present five years or longer and still remains small and sharply circumscribed.

*Early age incidence.* Approximately four fifths of the reported cases occur before the age of forty.

*Relatively equal sex incidence.* Several series of cases indicate that the tumor occurs in females with a frequency as great as or even greater than that in males.

*Low metastasizing power.* Metastases have only rarely been demonstrated in adjacent lymph nodes. The evidence indicating remote hematogenous metastases is not as yet clearly definitive. Generalized metastases comparable to those commonly observed in the terminal stages of cancer of other organs have not been described.

*Surgical resectability.* Technical difficulties in surgical resection are almost invariably due to the inflammatory complications of prolonged bronchial obstruction rather than to mediastinal invasion or lymph-node involvement.

*Low operative mortality rate.* The operative mortality rate is approximately 10 per cent, depending somewhat on whether a lobectomy or a total pneumonectomy is performed.

*Permanent cures by resection.* Patients surviving resection appear to be permanently cured. No case has been reported in which the patient died of recurrence or metastases.

*Central location.* With rare exceptions, the tumors occur in the large bronchi near the hilum and are thus within easy reach of the bronchoscope.

*Typical histologic pattern.* Small uniformly sized cells are arranged in columns, showing few if any mitoses. Bone formation is not unusual.

If tumors with these characteristics are set aside, it will be found that other bronchogenic tumors portray more typically the picture of carcinoma as established for other organs. Such tumors grow rapidly, varying with the degree of cellular differentiation; the greatest age incidence is from forty to sixty years; the sex incidence is predominantly male (as in cancers of the lip, tongue and stomach); metastases are frequent, again varying with cellular type; surgical resectability, the mortality rate of resection and the permanence of surgical cure are discouraging, favorable results depending on early diagnosis, and recurrence or metastases taking a heavy toll among patients surviving operation; the site of the primary lesion may be peripheral or central, varying in relation to the type of cell; the histologic patterns are those of epidermoid carcinoma, adenocarcinoma or undifferentiated carcinoma, as found in other organs.<sup>2</sup>

Controversy regarding these tumors is concerned with definitions and interpretations rather than with the observational facts listed above. It is not the purpose of this review to defend any thesis relative to the nature of bronchial adenomas, or to criticize any proposed system of nomenclature. One point, however, seems sufficiently obvious: if cases of so-called "adenoma" are mingled with cases of other bronchogenic tumors in a study from which conclusions are drawn regarding prognosis or therapy, this fact should be clearly stated by the author. Compilations of the results of surgical therapy<sup>3</sup> or of x-ray therapy<sup>4</sup> are of doubtful value, or may be positively misleading if this simple rule is not observed.

All articles in this series will be published in book form; the current volume is *Medical Progress: Annual, 1940* (Springfield, Illinois: Charles C. Thomas Company, 1941. \$4.00).

## WAR INJURIES OF THE CHEST

### Statistics

A recent personal communication relative to chest injuries in the present war stated that the mortality in chest cases received from the evacuation following the Battle of France was only 5 per cent, or equal to only one third the mortality in the South African campaign of 1900, which was the lowest hitherto recorded, and one fifth that in World War I.

It is important to realize just what such figures mean, and the following quotation from a book<sup>5</sup> published in 1877 is so pertinent that further comment is unnecessary.

*Apparent increase in ratios of mortality in certain wounds.*—The following fact serves to illustrate the difference which there may appear to be in the relative fatality of certain wounds under hospital treatment, owing to differences in the distances of the hospitals from the places of fighting. During the Crimean War the percentage of fatality of chest wounds, all kinds of chest wounds being taken together, in the French military hospitals was 30.7 per cent. This ratio of mortality was almost the same as it was in the hospitals of the British army. In the French hospitals during the Italian campaign of 1859, however, the mortality was only 18.9 per cent. The altered rate of mortality shown in the hospital returns of the latter war cannot be said to have been due to any diversity in the nature of the wounds inflicted in the field, nor in that of the treatment adopted in the hospitals; it was obviously attributable to the fact that the field-hospitals in the Crimea were close to the places where the wounds were received, while in the Italian War they were situated for the most part at a considerable distance from them. In the Crimea, the patients were received into the ambulances shortly after their wounds had been inflicted; in Italy, owing to the largeness of the number of wounded resulting from the principal battles, and the consequent difficulties of transport, together with the distance of the hospitals, many of the severer cases did not live long enough to be admitted into hospital for treatment,—they died on the field of action itself. The chest wounds among the "killed in action" in Italy were increased in number; the deaths among those treated in hospital were, in proportion, lessened in number. The absolute mortality from wounds of the chest was probably very similar in both the Italian and Crimean wars.

### Body Armor

Full on his breast the Trojan arrow fell  
But harmless bounded from the plated steel.

Pope: *Translation of the Iliad*.

Body armor is used by police officers and agents of the Federal Bureau of Investigation in certain specialized situations. It furnishes good protection from missiles up to velocities of 1000 feet per second. Many attempts have been made to devise a practical body armor for modern warfare.<sup>6</sup> Obviously, no body armor with a weight that is sup-  
portable can be effective against high-velocity direct axial hits.

There seems to be little doubt that body armor can be used to advantage in specialized situations of modern warfare. The high fatality of chest and abdominal injuries, the frequency of injury from projectiles of low velocity and the transportation of troops by motorized equipment rather than by foot all argue for its use. It seems probable that any appreciable reduction in the mortality rate of chest injuries is apter to be achieved by preventive measures of this type than by more efficient methods of evacuation of the wounded.

### Blast Injuries

Longmore<sup>5</sup> in 1877 referred to injuries resulting from the "disturbance by actual molecular agitation produced by the violent impulse of the air," and to "vibratory disturbance of the internal organs near to the surface on which the impact of the projected gas is directly received." He described a terrific explosion of magazines of gunpowder and munitions of war in the French siege park and the adjoining English siege-train enclosure on November 15, 1855, as follows:

There were large numbers who, though not struck by any solid projectile, nor visibly wounded by the impulsive force of the explosion, were yet more or less seriously contused and injured by it. Some suffered from rupture of superficial blood-vessels of the air-passages and lungs, others from mischief to the organ of hearing. Especially prevalent, however, was shock to the general nervous system, and there could be little doubt, from observation, that this was not merely the result of panic but was largely due to actual physical concussion and contusion.

Blast injury is being discussed as a new entity in the present war, probably because of the frequency of its occurrence as a result of bombing from the air. Sutherland<sup>7</sup> describes the blast wave as a spherical shell of compressed air immediately surrounding the explosion. In the compression part of the wave, pressures up to 200 atmospheres have been observed in bomb explosions. The elasticity of compressed air tends to make it recover its original state, and in this way it tends to overshoot its mark so that although the outside shell is compressed a shell of rarefied air is left behind.

The wave of compressed air travels at an enormous speed (with a 60-pound charge, the velocity at thirty feet from the source has been recorded as 1500 feet per second). The duration of the wave of high pressure at any one point is approximately 0.006 second, and of the following phase of low pressure, 0.03 second, varying with the charge and the distance from the source.<sup>8</sup>

The impact of this wave on the human body causes death without signs of external injury. Sometimes there is a small amount of blood trickling from the nose. Capillary hemorrhage

and even laceration of the alveolar walls may be observed at autopsy. If death does not occur immediately, symptoms may appear as late as two to five days after the injury. Cough, shortness of breath and blood stained sputum result from the hemorrhagic exudate into alveolar and interstitial tissue.

Many reports of blast injuries and experimental studies on the mechanism involved are appearing in current English journals.

## ESOPHAGUS

### *Carcinoma*

The relatively recent advance in the surgical management of carcinoma of the esophagus is pointed out by Adams.<sup>9</sup> Before 1934, only in the celebrated case treated by Torek did the patient survive operation by more than two years. Thirteen other technically successful cases are on record, but the patients died of recurrence or metastases.

Since 1938, successful resections on 34 patients have been compiled by correspondence with twelve American surgeons. Of these, 20 are living, and about 50 per cent of the total of sixty eight operations were successful.

It may be stated without qualification that surgery offers a reasonable chance of arresting carcinoma of the esophagus. Palliative results may be secured when permanent arrest is impossible. The value of this achievement is more apparent if it is realized that carcinoma of the esophagus is fourth in frequency of all malignant tumors occurring in men over twenty years of age. It is surpassed in frequency only by cancer of the stomach, lung and rectum.

The procedure of esophageal resection is far from standardized, and at the moment calls for a combination of techniques derived from gastrointestinal, thoracic and plastic surgery. In general, two quite distinct procedures are available, the choice depending on the level of the carcinoma. Approximately 45 per cent of the tumors are located in the lower third of the esophagus. By a trans pleural approach, the diaphragm is divided, and the cardiac end of the stomach, as well as the esophagus, is mobilized. Resection of the tumor bearing area is followed by elevation of the fundus of the stomach into the pleural cavity and anastomosis with the lower end of the divided esophagus, thus re-establishing the continuity of the digestive tract. This operation is also being successfully employed for carcinomas of the cardiac end of the stomach that previously have been considered inoperable when approached by the abdominal route because of extension up the esophagus, or that, if resectable from below, have required a total gastrectomy.

Carcinoma involving the upper two thirds of the esophagus demands a more complicated and mutilating procedure. No operation has been devised that will permit an internal reconstructive resection. The Torek procedure, with modifications, remains the only feasible one. Following the resection of the tumor bearing area, the upper end of the esophagus is drawn out through a cervical incision and is left as an end esophagostomy. The lower end is inverted into the stomach after resection of the lymph nodes at the cardioesophageal angle. A preliminary Beck-Jianu gastrostomy brought well above the costal margin provides for feeding and may be connected with the cervical stoma by a rubber tube. Patients swallow well chewed food quite satisfactorily through such a temporary artificial esophagus. The permanent goal, however, is the construction of a skin tube joining the cervical esophagostomy and the gastrostomy openings.

The execution of details in this complicated program has varied greatly, and further experience will undoubtedly point the way to simpler methods. At the present time, its successful application calls for versatility and judgment on the part of the surgeon, and patience as well as courage as the contribution of the patient.

### *Congenital Atresia*

A study of 32 cases of congenital atresia of the esophagus has been presented by Lanman.<sup>10</sup> There was a fatal outcome in all the 30 operative cases, but it is evident that considerable progress along rational lines has been made. Lanman recommends a direct anastomosis if possible, otherwise, closure of the tracheoesophageal fistula is advised as the first step. As soon as conditions permit, the subsequent procedures are, first, the exteriorization of the upper esophageal segment and, secondly, an anterior gastrostomy. I have recently had the opportunity of examining a well-developed and well-nourished child at the University of Minnesota Hospital whom Dr Nathaniel L. Leven has brought well into the second year of life by the latter procedure. The problems of the construction of an artificial esophagus in this child are being postponed until a suitable age.

Lanman confesses that he dreads to commit an infant to the sort of existence that this deformity entails, and I must admit that this very consideration has led me to limit my own efforts in dealing with congenital atresia to attempts at direct anastomosis. Needless to say, they have been uniformly unsuccessful, but perhaps technically progressive.

An indirect report has reached me that a successful anastomosis has been achieved at the University of Michigan by Dr Cameron Haight. If

this report is confirmed, the score will be even for the two methods of approach.

Other anomalies of development are frequently associated with atresia of the esophagus and tracheoesophageal fistula. Lanman records in his series 7 cases of associated anomalies, which if not treated by operation were in themselves incompatible with life. In working with such infants, one not infrequently recalls the interpretation of Oliver Wendell Holmes:

Many affections which art has to strive against might be easily shown to be vital to the well-being of society. Hydrocephalus, tabes mesenterica, and other similar maladies are natural agencies which cut off the children of races [that is, strains] that are sinking below the decent minimum which nature has established as the condition of vitality, before they reach the age of reproduction. They are really not so much diseases, as manifestations of congenital incapacity for life; the race would be ruined if art could ever learn always to preserve the individuals subject to them. We must do the best we can for them, but we ought also to know what these "diseases" mean.

### Cardiospasm

The true nature of the disorder of the cardia associated with dilatation of the esophagus has been under discussion for years. Mosher<sup>11</sup> concluded that the fundamental lesion was not spasm but fibrosis of the terminal portion of the esophagus secondary to inflammatory changes starting in adjacent organs. The theory of achalasia of the cardiac sphincter associated with the name of Hurst is well known, but leaves the matter as a "chronic and progressive lesion of Auerbach's plexus," which is still far from satisfying.

An interesting concept has been proposed from Brazil (Etzel<sup>12</sup>), where the disease is said to occur with great frequency, and almost exclusively, among poor country people. Etzel is convinced that not only megaesophagus but megacolon and other associated conditions are the manifestations of a degenerative neuropathy of the intramural part of the autonomic nervous system caused by chronic and incomplete deficiency of vitamin B<sub>1</sub>. Evidence to support this hypothesis is derived from histologic studies and animal experimentation. Citation is made of MacCarrison's work describing enteric lesions in B<sub>1</sub> avitaminosis, in which lesions of a degenerative type were disclosed in Auerbach's plexus.

If this hypothesis can be confirmed, it is necessary to postulate a subclinical avitaminosis producing irreversible degeneration of certain cells of the autonomic system. The known tendency for the onset of the clinical syndrome to be associated with anxiety states or psychic trauma suggests that psychosomatic channels simply provide the trigger mechanism.

The treatment of the disease is usually satisfactorily carried out by dilatation. In complicated or intractable cases, an esophagocardioplasty may be recommended. Even with complete symptomatic relief of the obstructive symptoms, the megaesophagus persists.

### BRONCHIECTASIS

Two important studies throw light on the prognosis of untreated bronchiectasis and indicate that the extension of radical surgery in the treatment of this disease has been justified by the poor outlook under other forms of therapy. Perry and King<sup>13</sup> issued a report based on 260 patients not treated by major operations. Of a group of 211 patients traced, 66 are known to be dead, a mortality rate of 31 per cent. Forty-one per cent of these had died within five years of the onset of symptoms. The series includes recently diagnosed cases, so that the mortality rate reflects only partly the toll that may be assumed in a late follow-up study. Seventy-eight per cent of the deaths were directly attributable to the disease.

Bradshaw et al.<sup>14</sup> report on 171 patients with bronchiectasis, excluding those cases attributable to foreign body or pulmonary abscess, and excluding those patients treated by major surgery or regular bronchoscopic aspirations. In these patients, the diagnosis was established between the years 1925 and 1935. Fifty-nine, or 34.5 per cent, died from bronchiectasis or its complications. The average duration of life in the dead patients from the onset of symptoms was thirteen and a half years.

The conclusion is justified that bronchiectasis is a fatal disease. Death occurs most commonly from pneumonia, and also from pulmonary abscess and gangrene, brain abscess, empyema and, rarely, hemorrhage.

## CASE 27351\*

### PRESENTATION OF CASE

A 3½ pound newborn infant was admitted four hours after delivery because of prematurity, having been born early in the eighth month of pregnancy, by spontaneous breech delivery after seven hours of labor.

The family history was noncontributory. The mother had been well during pregnancy, and the cause of the premature delivery was not known.

At birth, the baby responded well, had a good cry, and allegedly was not cyanotic. Physical examination on entry revealed a small, fairly well developed, moderately cyanotic infant whose temperature was 95.6°F. The respirations were regular, but there was slight dullness posteriorly, with a few scattered rales at both bases. The heart and abdomen seemed normal.

Examination of the blood showed a red cell count of 5,850,000, and a white cell count of 21,600 with many young cells of both the white and red series. The differential count was 40 per cent polymorphonuclears, 48 per cent lymphocytes, 5 per cent monocytes, 6 per cent eosinophils, and 1 per cent basophils, with normal platelets.

The baby was placed in a high oxygen concentration in a heated cradle, and whenever taken out became cyanotic. Lumbar puncture on the morning after admission revealed grossly bloody fluid. During the second hospital day, respirations became irregular, the color poor, and the cry weak. Respirations ceased that afternoon, twenty-four hours after birth.

### DIFFERENTIAL DIAGNOSIS

DR. THEODORE H. INGALLS: Here we have a baby born prematurely by breech extraction, weighing 3½ pounds at birth, who seemed relatively normal after delivery. Subsequently, he developed increasingly grave spells of cyanosis; dullness and rales appeared at the bases of the lungs. The patient rapidly failed and died within twenty-four hours.

The most striking symptom we have to consider is cyanosis. Cyanosis occurs when the concentration of reduced hemoglobin in the blood reaches

approximately 5 gm per 100 cc. It is well to bear in mind that cyanosis is not necessarily synonymous with anoxia of tissue cells, although of course it may be the precursor. The first possible cause of cyanosis in this case is the interference with continuous respiratory exchange, which to some degree at least is a normal happening at birth. Although some babies are never cyanotic at birth, many are quite blue, and many are absolutely livid before they take their first gasp. In this particular case, however, we are given to believe that neither the attending physician nor, subsequently, the nurses were alarmed about the baby's color.

Secondly, cyanosis can be caused by cardiac and pulmonary disturbances, such as the admixture of venous blood with arterial blood through pathologic openings associated with congenital heart disease. Except for the cyanosis, no other findings in this case draw one's attention particularly to the heart. Atelectasis may be a cause of cyanosis. However, simple atelectasis as the only cause of the failure of the lungs to expand is not a satisfactory diagnosis in my opinion. Gross abnormalities of the bronchial tree or the inspiration of such large amounts of mucus and amniotic fluid that the baby practically drowns would result in atelectasis, but one would expect the appearance of the symptoms soon after birth.

This brings me to the final and most serious cause of cyanosis—cerebral injury, which may result from asphyxia, trauma, hemorrhage, edema or a combination of these. In fact, they are usually combined. Following asphyxia, for example, the first result is congestion, then edema, then necrosis and finally hemorrhage. In this case, a very tangible suggestion that there was cerebral injury is grossly bloody lumbar puncture. Such a finding is also consistent with the fact that this baby was distinctly premature. The fragile underdeveloped tissues of the premature infant make him particularly susceptible to cerebral injury, so that he is frequently unable to withstand even the normal stress and strain and anoxemia of delivery. In this case, birth was by breech extraction, which is a distinct central-nervous system hazard.

The symptoms of cerebral hemorrhage depend on the size, the site and the propagation of the hemorrhage. If there is slowly accumulating subarachnoid bleeding, there may be irritation of the cortex, and convulsions may ensue. If there is subtentorial bleeding, cyanosis may be the predominant symptom. In this case, a suggestion that this may have occurred is the fact that the baby's fontanelle is not mentioned as bulging. Finally, we have the findings in the chest to in-

\*This case is published through the courtesy of the Children's Hospital.

terpret—dullness and rales at the bases of the lungs, which I should think represented pulmonary edema due to injury of the vagal nuclei; if both vagi are injured in the experimental animal, pulmonary edema follows consistently in the space of twelve to twenty-four hours. It is not possible to rule out pneumonia, although I am under the impression that pulmonary edema is more often misdiagnosed as terminal pneumonia than the reverse. I shall be interested in the pathological report on the lungs, however.

Finally, I think I should merely mention vitamin K deficiency in passing as being a possible, or at least a contributory, cause of bleeding, although in this case the only clinical suggestion of bleeding is the bloody lumbar puncture.

DR. ELI C. ROMBERG: It would have been interesting to know whether the baby had any slowing of the pulse and of respirations, because all the premature infants who have those symptoms and intermittent cyanosis, and die within thirty-six hours, have subtentorial hemorrhage.

DR. HAROLD L. HIGGINS: The striking thing about this case to me is that we are dealing with a premature infant, and I cannot help believing that a most likely cause of death was the inability of the child's brain to maintain normal respiration and circulation, because of immaturity. I realize that an intracranial hemorrhage was suspected, because a lumbar puncture was done; but I wonder if there was bulging of the fontanelle or other signs of increased pressure. Again, was the blood found on spinal puncture due to trauma? I should certainly suspect vitamin K deficiency as a contributing cause of the hemorrhage. My diagnosis would be prematurity, with probable cerebral hemorrhage, hemorrhagic disease of the newborn and traumatic injury at birth.

#### CLINICAL DIAGNOSES

Prematurity.  
Cerebral hemorrhage.

#### DR. INGALLS'S DIAGNOSES

Prematurity.  
Cerebral hemorrhage (? subtentorial).  
Pulmonary edema (? pneumonia).

#### ANATOMICAL DIAGNOSES

Pneumonia (pneumococcus).  
Pneumococcemia.  
Pulmonary edema and congestion.  
Aspiration of amniotic-sac contents.  
Cerebral hemorrhage, subarachnoid and subdural.  
Prematurity.

#### PATHOLOGICAL DISCUSSION

DR. SIDNEY FARBER\*: I think the fact that so many possibilities have been mentioned in the thorough review that Dr. Ingalls gave, in addition to the fact that different suggestions have been made concerning what the infant might have had, is characteristic of the problem of the premature infant. This infant weighed  $3\frac{1}{2}$  pounds, and died twenty-four hours after entering the hospital. At autopsy, there was diffuse hemorrhage beneath the arachnoid and beneath the dura, and a hematoma of the scalp. So much for the cerebral difficulty. There was a very early pneumococcal pneumonia. The pneumococcus was grown from the heart's blood and the lung. Furthermore, in the lungs, there was evidence of aspiration of amniotic-sac contents and considerable congestion and edema. Fibrin thrombi were found microscopically in many organs of the body, a finding that may be explained by the pneumococcemia.

I should like to say before going farther that prematurity or immaturity of tissues alone is in my opinion an unsatisfactory cause of death or of any important disturbance in a baby weighing  $3\frac{1}{2}$  pounds. Although immaturity of the tissues is usually demonstrable, particularly in the brain, I believe that a baby of this weight has achieved enough maturity of development to get along perfectly well and to live without having serious symptoms referable to immaturity of tissues.

The meninges were extremely thin. The superficial vessels were congested, and there was diffuse subarachnoid hemorrhage scattered over the various brain surfaces. Some of this appeared to be quite recent and it is probable that not all the hemorrhage took place during labor. There was no collection of blood over the cerebellum or brain stem, sites of involvement that would cause much more intense cyanosis or much more difficulty with respiration than the type of hemorrhage encountered here. If we find no more cerebral hemorrhage than we found here, we must look elsewhere for a satisfactory explanation of the cyanosis. A premature baby rarely suffers from tentorial tears or rupture of the great veins of Galen. Gross tears of the dural membranes do not occur so frequently as in full-term babies.

The mode of entrance of the pneumococci was by way of the aspirated amniotic contents, which had been infected with the organisms from the birth canal of the mother.

In summary, there was diffuse cerebral hemorrhage as a part of a general birth injury. This

\*Assistant professor of pathology, Harvard Medical School; pathologist, Children's Hospital.

was a contributory cause of death and of the cyanosis. The immediate cause of death was the pneumococemia, which spread to the blood stream from the lungs. The pneumococcus apparently entered the lungs with aspirated amniotic-sac contents, which were infected from the birth canal of the mother.

DR. HIGGINS: One wonders about infection as the result of mouth-to-mouth insufflation.

DR. FARBER: That would be quite possible as the means of entrance of the organisms.

A PHYSICIAN: Is the white-cell count of 22,000 high?

DR. INGALLS: I should consider it moderately high for a premature infant; it did not strike me as pathognomonic of infection.

DR. HIGGINS: Do you not think, Dr. Farber, that one can get functional immaturity without pathological immaturity?

DR. FARBER: I am quite sure one could. My point, Dr. Higgins, is that, although immaturity of the respiratory center is of importance and is one of the factors that combined with others may bring about atelectasis and respiratory difficulty, immaturity alone is not explanation enough for respiratory disturbance in a premature baby.

## CASE 27352

### PRESENTATION OF CASE

*First Admission.* A forty-three-year-old American roofer entered the hospital complaining of a skin rash.

Three years before entry, he noticed a slightly raised reddish itching patch about 1 cm. in diameter on the inside of the right thigh. Since then, similar lesions had appeared all over his body, including the abdomen, back, chest and the flexor surfaces of the lower legs and arms. No lesions had ever appeared on the extensor surfaces of the arms or legs or on the head. The lesions were usually round at the onset and finally became completely irregular. Some of them developed brown crusts; others became rough, without crusts. The lesions usually lasted about three weeks and left no marks. There was no seasonal distribution. Three months before entry, a crusting lesion appeared in the right groin. This swelled considerably and then disappeared.

The family, marital and past histories were non-contributory.

Physical examination showed a well-developed and well-nourished man lying in bed without discomfort. Over the back of the neck, the flexor surfaces of the arms, and over the back and abdo-

men, there were slightly raised pink lesions varying from 1 to 4 cm. in diameter. Some were irregularly bordered, others sharply outlined. Many showed only slight scaling, whereas others had a grayish crust.

The temperature was 98.4°F., the pulse 80, and the respirations 20.

Examination of the urine was negative. The blood showed a red-cell count of 5,090,000 with a hemoglobin of 75 per cent, and a white-cell count of 5650 with 74 per cent polymorphonuclears.

An x-ray film of the chest showed that the right lung field was slightly less radiant than the left, and that the intercostal spaces were narrowed. There was evidence of thickening of the pleura from the apex to the diaphragm, but no definite areas of consolidation within either lung. The lung roots were slightly thickened. There were no mediastinal masses.

On the fifth day, a biopsy of one of the skin lesions was taken, and an axillary lymph node removed. The skin showed the histologic structure of mycosis fungoides, but the axillary lymph node showed only chronic inflammation. The patient was discharged on the following day, after having received x-ray treatment and one intravenous injection of arsphenamine.

*Final Admission* (approximately four years later). Following discharge, he was seen fairly often, receiving on the average one x-ray treatment a month. The larger lesions were fairly well controlled by this treatment. Seven months before entry, while in Maine, he developed a very large lesion on the right thigh. He went to another physician, who gave him three doses of very deep x-ray therapy, the last one about a month before entry. This treatment, according to the patient, "knocked the stuffing out of him," and he was forced to go to bed. He was very weak and had a very poor appetite. During the month before this admission, he developed slight shortness of breath, and about a week later, an abscess in the left axilla, which discharged spontaneously.

Physical examination showed an emaciated, anemic, cachectic man, with generalized, blotchy, red and pigmented, scaly, macular areas, and also several infiltrated plaques and nodules over the skin. There was generalized lymphadenopathy. The mucous membranes were pale but showed no lesions. There was slight bronchovesicular breathing over both bases, but no rales. The heart sounds were of poor quality. The blood pressure was 100 systolic, 55 diastolic. The liver edge was felt 5 cm. below the costal margin. The spleen was felt 5 cm. below the umbilicus and in the flank.

The temperature was 102°F., the pulse 110, and the respirations 20.

Examination of the urine was negative. The blood showed a red-cell count of 3,190,000 with a hemoglobin of 65 per cent, and a white-cell count of 5400 with 64 per cent polymorphonuclears. The platelets were markedly decreased. The red blood cells showed mild achromia. A blood Hinton reaction was negative. The bleeding time was 3 minutes.

An x-ray film of the chest was negative.

The patient was given fluid parenterally. The temperature remained fairly elevated, ranging between 100 and 102°F. The red-cell count dropped to 1,160,000, with a hemoglobin of 35 to 40 per cent. The white-cell count dropped to 2600 and finally to 1250. A smear showed marked achromia and variations in size and shape of the red blood cells. No platelets or young forms were seen. There was approximately 70 per cent polymorphonuclears. The patient failed rapidly, and died sixteen days after admission.

#### DIFFERENTIAL DIAGNOSIS

**DR. WALTER F. LEVER:** A differential diagnostic discussion of the cutaneous lesions is superfluous, because the diagnosis "mycosis fungoides" had already been established by histologic examination, four years before the patient's death. In addition to the cutaneous eruption, the patient presented a generalized lymphadenopathy, a marked increase in the size of the liver and spleen, and a severe anemia, leukopenia and thrombocytopenia. The question arises whether any or all these manifestations were caused by mycosis fungoides.

According to the present prevailing view, mycosis fungoides is a form of lymphoblastoma. Under lymphoblastoma are grouped all neoplasms derived from the stem cell, which is the mother cell of both the lymphatic and the reticulum cells. The infiltrate of mycosis fungoides contains, in varying proportions, stem cells and both types of cells derived from the stem cell, so that histologic examination may show stem cells, lymphoblasts, lymphocytes, reticulum cells and monocytes. In addition to these, a variety of other cells are usually present in the infiltrate, namely granulocytes (neutrophils, as well as eosinophils) fibroblasts, fibrocytes and plasma cells, all of which are mature. The latter group of cells represents merely an inflammatory reaction provoked by the neoplastic infiltrate. This inflammatory reaction is most pronounced in the early stages of the disease, so that histologic examination at that time may show only mature cells, as found in chronic inflammation. If the neoplastic process involves

mainly the lymphatic cells, mycosis fungoides may, histologically as well as clinically, resemble lymphocytic lymphoblastoma; if the infiltrate is made up mainly of reticulum cells, the histologic picture of mycosis fungoides may resemble reticulum-cell lymphoblastoma; if both types of cells are present in a more or less equal proportion, mycosis fungoides may histologically resemble Hodgkin's disease. There even exists strong evidence that mycosis fungoides is actually identical with any of the three above-mentioned types of lymphoblastoma, and that it differs from them only clinically in its tendency to primary and preponderant localization in the skin.

The classification of mycosis fungoides into the group of lymphoblastomas and the realization of its close relation to, if not identity with, lymphocytic lymphoblastoma, reticulum-cell lymphoblastoma and Hodgkin's disease explain the occasionally encountered widespread neoplastic involvement of internal organs in mycosis fungoides.

Applying this concept to the present case, I believe that histologic examination of some lymph nodes showed neoplastic changes involving either the lymphatic or the reticulum cells, or both types of cells simultaneously, whereas other lymph nodes showed only an inflammatory infiltration, just as the cutaneous lesions of mycosis fungoides may present either a neoplastic or merely an inflammatory infiltrate.

The considerable enlargement of the liver and spleen was, in my opinion, also due to an infiltration with neoplastic lymphoblastic cells. Other causes than lymphoblastoma can be ruled out fairly well. The tremendous size of the spleen readily rules out the possibility of cirrhosis of the liver, or of cardiac decompensation or amyloidosis. Furthermore, there were no collateral symptoms to substantiate these diagnoses.

There are three possible explanations of the aplastic anemia. First, the aplastic anemia may have been due to lymphoblastic involvement of the bone marrow (myelophthisis). Secondly, it may have been merely a terminal, nonspecific, toxic process caused by cachexia, and thirdly, it may have been the result of the extensive x-ray therapy. In mycosis fungoides, bone-marrow changes are fairly frequent but, as a rule, are present only in a mild degree. They occur mainly in the form of an increase in the number of stem cells and their immature derivative cells. These bone-marrow changes of mycosis fungoides may occur with or without changes in the number and appearance of the circulating blood cells. Yet, one should think that an unusually severe involvement, which in the end completely prevented the

mission of red and white blood cells into circulation, would have led to an appearance of immature blood cells during the preceding weeks. In view of the absence of qualitative changes in the peripheral blood, I am inclined to believe that the aplastic anemia was a nonspecific toxic terminal process. The extensive x-ray radiation may have been a contributory factor. I believe it will be impossible to determine how much either factor was responsible. In any case, I should expect the bone marrow to show the usual appearance in aplastic anemia (fatty, gelatinous degeneration, and microscopically almost complete absence of red cells, myelocytes and megakaryocytes).

In conclusion, I want to point out the clinical resemblance of this case of mycosis fungoides to one of Hodgkin's disease. I believe that the resemblance to Hodgkin's disease will be borne out by the histologic examination.

#### CLINICAL DIAGNOSIS

Mycosis fungoides

#### DR. LEVER'S DIAGNOSES

Lymphoblastoma (mycosis fungoides, ? Hodgkin's disease) of the skin, lymph nodes, liver and spleen

Aplastic anemia (terminal toxic, with x-ray irradiation possibly a contributory factor)

#### ANATOMICAL DIAGNOSES

Mycosis fungoides

Aplastic anemia

Pulmonary infarction, septic, multiple, bilateral

Infarct of spleen

Operative wound biopsy, left epitrochlear gland

Arteriosclerosis, slight, aortic

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY. Dr. Lever's predictions proved very close to what we actually found at autopsy. The primary diagnosis had, of course, already been established histologically by the biopsy. There is, however, great variety among these cases in the type of infiltrating cells and in the degree of involvement of the internal organs. In this case, there was obvious lymphomatous involvement of a large proportion of the

lymph nodes of the body and also of the spleen. The liver, however, did not contain neoplasm and showed only a mixture of fatty infiltration and central necrosis of the lobules. It was not strikingly large, weighing 1800 gm., whereas the spleen, which weighed 1100 gm., is well up to the size seen in leukemia. Dr. Lever was correct in stating that the bone marrow would not be replaced by tumor cells but would be consistent with aplastic anemia. It showed a great diminution in the hematopoietic elements of both the red cell and white-cell series, a slight increase in the number of fat cells and a considerable degree of so-called "gelatinous degeneration." There were no other significant findings.

From the point of view of histologic classification, the neoplastic cells all showed differentiation in the direction of relatively mature lymphocytes. It would have been impossible, for instance, to distinguish sections of the spleen and lymph nodes from those of corresponding tissues from a case of lymphoid leukemia. As Dr. Lever has pointed out, this is by no means always so. Even when there is a marked generalized lymphadenopathy, one is often disappointed that a lymph node removed for biopsy shows only a nonspecific hyperplasia and nothing on which a diagnosis of lymphoma can be made. The diagnosis of the disease must usually be made from a biopsy of the skin itself. In the early stages, this is often extremely difficult, and sometimes several biopsies must be taken before the diagnosis can be established. The period of time during which the process may remain localized to the skin is often, in comparison with other lymphomatous processes, astoundingly long. Five and ten years are not uncommon figures, and intervals as long as fifteen years are sometimes observed.

I can go no farther than Dr. Lever did in explaining the cause of the aplastic anemia. It may have been some effect of the neoplastic process, or of the chronic sepsis that so often supervenes in the terminal stages of this disease when the skin tumors break down and ulcerate. Prolonged x-ray exposure can certainly produce this type of bone marrow, and in the course of years these patients often receive a formidable amount of radiation.

## PREMARITAL MEDICAL EXAMINATIONS

THE Massachusetts Legislature has passed and Governor Saltonstall has signed, as noted elsewhere in this issue of the *Journal*, a premarital examination law that is as well conceived and as sound as that in any state. Great credit is due to Representative Leslie B. Cutler, of Needham, without whose whole-hearted interest and intelligent efforts this bill probably would not have passed. The Massachusetts Medical Society and other organizations worked hard in support of Mrs. Cutler.

This bill provides that no couple may receive a marriage license until they can provide the town or city clerk who issues it certificates showing that a registered practitioner of medicine has examined each party and has explained his findings to both

parties. A blood test for syphilis is to be part of the examination. A law with similar provisions has been in successful operation in Virginia for nearly two years.

The wording of the bill makes it mandatory for the physician to find or exclude any "infectious disease declared by the State Department of Public Health to be dangerous to the public health." This means that all so-called "reportable diseases" must be considered. The bill in no way changes present laws in connection with the reporting to local boards of health of cases found to have any of these infections.

The law makes no provision for halting any marriage; but if its provisions are carried out conscientiously by the profession, men and women will be prevented from marrying obviously sick persons without being so informed in advance. Furthermore, if disease is found, an opportunity is provided for the treatment of the infected prospective partner and for the protection of the other after marriage.

The bill puts a very great responsibility on those members of the profession who will make these examinations, but the duty should not be shirked and overcharges should be avoided. Nominal charges for very careful examinations might well result in creating friendships that would lead to many calls for obstetric or other medical service in later years. Furthermore, such an approach would be peculiarly effective at the time when nearly all couples, no matter how wealthy they may be, feel poor because of the large expenses necessarily incurred in setting up a home.

Nearly all premarital laws in other states focus their emphasis on "blood testing" and also attempt to prevent marriage under certain conditions. The difficulty with such provisions lies in the impracticability of setting up fair and workable laws that will cover all the various contingencies. This difficulty is recognized in some states, such as New York, by providing that certain judges have the power to authorize marriages otherwise forbidden when "public policy" makes such a step seem proper. A difficulty with this is that judges as a class are not trained in medicine or public health

id must act on information secured from physicians. It seems much better to leave the whole matter to physicians, and to remove all possible impulses beyond the determination and presentation of medically determined facts

## PROCUREMENT AND ASSIGNMENT AGENCY

ALTHOUGH over 160,000 physicians have filled out the questionnaires forwarded by the Committee on Medical Preparedness of the American Medical Association, and although these invaluable data concerning professional training, experience and availability have been transferred to punch cards at the headquarters of the association, as yet no authority has been created with the power to make use of this material

As pointed out in *War Medicine*,\* the future needs for medical personnel will probably include the following physicians for the United States Army, Navy and Public Health Service and other governmental agencies, physicians for the local and appeal boards created under the Selective Service Act, physicians for civilian medical care and defense, physicians for aid to Britain, requested by the American Red Cross, physicians for industry, physicians for rehabilitation, and physicians for state and county medical and public health organizations. The procurement and assignment of men to fill these positions to best advantage is a tremendous task, but one that could be properly handled if the punch card data were utilized. For this reason, the House of Delegates, at the recent meeting of the American Medical Association, passed a resolution urging the establishment, by the United States government, of a central authority, to be known as the Procurement and Assignment Agency, to provide, if necessary, for efficient and adequate medical staffing of all governmental, civilian and industrial services. The membership of such an agency would include representatives of the civilian medical profession

Copies of this resolution were forwarded to the

various governmental heads in Washington who are concerned with the problems of medical care, and it is hoped that prompt action will be taken and that means will thus be created for the provision of a wisely selected medical personnel in any emergency

## MEDICAL EPONYM

### BENCE JONES PROTEIN

A paper, "On a new substance occurring in the Urine of a patient with Mollines Ossium," was read before the Royal Society on April 22, 1847, by Henry Bence Jones (1813-1873), physician to St George's Hospital. This appears in the *Philosophical Transactions of the Royal Society of London* (138, Pt 1 55-62, 1848)

On the 1st of November 1845 I received from Dr *Watson* the following note with a test tube containing a thick, yellow, semi-solid substance — The tube contains urine of very high specific gravity when boiled it becomes highly opaque, on the addition of nitric acid it effervesces assumes a reddish hue, becomes quite clear, but, as it cools assumes the consistency and appearance which you see heat relieves it. What is it?

A few hours afterward a specimen of the same urine, passed by a grocer forty seven years of age, who had been out of health for thirteen months was sent to me by Dr *MacIntyre*. He, being in attendance on the case with Dr *Watson*, had two days previously first observed the peculiar reactions of the urine.

The specimen of urine was slightly acid, specific gravity 1034, it contained a sediment consisting of crystalline phosphate of lime, oxalate of lime, and cylinders of fibrin. The urine became thick with heat from a deposit of phosphates, but cleared with a drop of acid. It gave no precipitate with an excess of nitric acid, unless left to stand, or unless heated and left to cool, when it became solid. This solid redissolved by heat, and again formed on cooling. Continued boiling with strong nitric acid evolved but little gas, and did not quickly hinder this reaction. Hydrochloric acid gave the same solid precipitate, soluble by heat. Strong acetic acid gave only a slight precipitate which redissolved by heat. Caustic potash and sulphate of copper gave a splendid bright blue, clear liquid, passing over when heated to claret colour.

January 2nd — The patient died. The following day I saw that the bony structure of the ribs was cut with the greatest ease, and that the bodies of the vertebrae were capable of being sliced off with the knife. For an account of the structure of the bone, see a paper by Mr *Dalrymple* in the third number of the *Dublin Journal*, August 1846.

The ultimate analysis of this substance may be represented by  $C_{48} H_{37} N_6 O_{15}$  or  $C_{40} H_{30} N_5 O_{12}$

Hence it is an oxide of albumen, and from ultimate analysis, it is the hydrated deuteroxide of albumen

The Massachusetts Medical Society and other organizations worked hard in support of Mrs. Cutler.

This bill provides that no couple may receive a marriage license until they can provide the town or city clerk who issues it certificates showing that a registered practitioner of medicine has examined each party and has explained his findings to both

parties. A blood test for syphilis is to be part of the examination. A law with similar provisions has been in successful operation in Virginia for nearly two years.

The wording of the bill makes it mandatory for the physician to find or exclude any "infectious disease declared by the State Department of Public Health to be dangerous to the public health." This means that all so-called "reportable diseases" must be considered. The bill in no way changes present laws in connection with the reporting to local boards of health of cases found to have any of these infections.

The law makes no provision for halting any marriage; but if its provisions are carried out conscientiously by the profession, men and women will be prevented from marrying obviously sick persons without being so informed in advance. Furthermore, if disease is found, an opportunity is provided for the treatment of the infected prospective partner and for the protection of the other after marriage.

The bill puts a very great responsibility on those members of the profession who will make these examinations, but the duty should not be shirked and overcharges should be avoided. Nominal charges for very careful examinations might well result in creating friendships that would lead to many calls for obstetric or other medical service in later years. Furthermore, such an approach would be peculiarly effective at the time when nearly all couples, no matter how wealthy they may be, feel poor because of the large expenses necessarily incurred in setting up a home.

Nearly all premarital laws in other states focus their emphasis on "blood testing" and also attempt to prevent marriage under certain conditions. The difficulty with such provisions lies in the impracticability of setting up fair and workable laws that will cover all the various contingencies. This difficulty is recognized in some states, such as New York, by providing that certain judges have the power to authorize marriages otherwise forbidden when "public policy" makes such a step seem proper. A difficulty with this is that judges as a class are not trained in medicine or public health

ons should be established Ether and iodine have been proved bactericidally to be as good as any other preparations and better than most, and the iodine solution costs less than 10 cents a pint, a figure much lower than those of other antiseptic solutions

This patient evidently was septic from the beginning, and it is quite likely that she was suffering from a pelvic phlebitis. The use of uroquinolone during the convalescence suggests that pyelitis was wrongly diagnosed. There is no excuse for allowing a patient who has had tenderness in the leg and an elevated temperature on and off for eighteen days to get out of bed. This sepsis, which was undoubtedly caused by an embolus, and which might have been prevented by conservative treatment, was due to poor medical care.

## COMMITTEE ON STATE AND NATIONAL LEGISLATION

The following is a transcript of House Bill No. 60, recently signed by Governor Saltonstall

**AN ACT** further regulating the filing of notices of intention of marriage, and the delivery of certificates of such intention and the return of unused certificates

Section 1 Chapter two hundred and seven of the General Laws is hereby amended by inserting after section twenty A, inserted by section three of chapter two hundred and sixty nine of the acts of nineteen hundred and thirty nine, the following new section

Section 20B Except as hereinafter provided, such notice of intention of marriage shall not be accepted by the clerk or registrar until he has received from each party to the intended marriage a certificate signed by a registered physician who has examined such party as hereinafter provided. If such physician, in making such examination, discovers evidence of any infectious disease declared by the state department of public health to be dangerous to the public health, he shall inform both parties of the nature of such infectious disease and of the possibilities of transmitting the same to his or her marital partner or to their children. Such examination shall include a standard serological test for syphilis and said test shall be made by a laboratory of said department or by a laboratory approved by it for such test.

Such certificate shall read as follows—I (name and address of physician), a registered physician of (city or town) in the commonwealth of Massachusetts on oath declare that on (day, month, year) I examined (name and address of party) in accordance with section twenty B of chapter two hundred and seven of the General Laws

The examination by such physician and the laboratory test shall be made not more than thirty days before the filing of the notice of marriage. Whoever fails to comply with this section shall be punished by a fine of not less than ten nor more than one hundred

dollars. In extraordinary or emergency cases where the death of either party is imminent or where the female is near the termination of her pregnancy, upon the authoritative request of a minister, clergyman, priest, rabbi or attending physician, the clerk or registrar may accept such notice of intention without having received the physician's certificate hereinbefore referred to

Section 2 Section twenty eight of said chapter two hundred and seven, as appearing in the Tercenary Edition, is hereby amended by striking out, in the third and in the eleventh lines, the words 'six months' and inserting in place thereof, in each instance, the words, 'sixty days,' so as to read as follows—

Section 28 On or after the fifth day from the filing of notice of intention of marriage, except as otherwise provided, but not in any event later than sixty days after such filing, the clerk or registrar shall deliver to the parties a certificate signed by him, specifying the date when notice was filed with him and all facts relative to the marriage which are required by law to be ascertained and recorded, except those relative to the person by whom the marriage is to be solemnized. Such certificate shall be delivered to the minister or magistrate before whom the marriage is to be contracted, before he proceeds to solemnize the same. If such certificate is not sooner used, it shall be returned to the office issuing it within sixty days after the date when notice of intention of marriage was filed.

Section 3 Section fifty seven of said chapter two hundred and seven, as so appearing, is hereby amended by striking out, in the second and in the fourth and fifth lines, the words 'six months' and inserting in place thereof, in each instance, the words, 'sixty days,' so as to read as follows—

Section 57 Whoever performs a ceremony of marriage upon a certificate more than sixty days after the filing of the notice of intention of marriage as set forth in such certificate, and whoever having taken out such certificate and not having used it fails to return it, within sixty days after such filing, to the office issuing the same, shall be punished by a fine of not more than ten dollars.

Section 4 This act shall not affect any certificate referred to in section twenty-eight of chapter two hundred and seven of the General Laws which was lawfully issued and outstanding upon the effective date of this act.

HENRY C. MARBLE, *Chairman*

## DEATH

**TRACY**—WILLIAM L. TRACY, M.D., of Pittsfield, died recently. He was in his sixty seventh year.

Born in Hartland, New Brunswick, he attended Fredrickton Normal School and the University of New Brunswick, and received his degree from McGill University Faculty of Medicine in 1908. He was treasurer and chief surgeon of Hillcrest Hospital, Pittsfield.

Dr. Tracy was a fellow of the Massachusetts Medical Society, the American Medical Association and the American College of Surgeons. He was president of the Pittsfield Surgeons Club and was treasurer of the Pittsfield Cancer Clinic.

His sister, two nieces and five nephews survive him.

## MISCELLANY

## AMERICAN MEDICAL DIRECTORY

About September 1, an information card will be sent from the headquarters office of the American Medical Association to every physician in the United States and Canada. The information secured is to be used in compiling the seventeenth edition of the *American Medical Directory*.

The directory is prepared at regular intervals in the Biographical Department of the American Medical Association. The last previous edition appeared in 1940. This volume is one of the most important contributions of the American Medical Association to the work of the medical profession in the United States; it has been especially valuable in the medical preparedness program. In it, as in no other published directory, are dependable data concerning physicians, hospitals, medical organizations and activities. The directory provides full information concerning medical colleges, specialization in the field of medical practice, memberships in special medical societies, tabulations of medical journals and medical libraries and, indeed, practically every important fact concerning the medical profession in which anyone might possibly be interested.

Before filling out the information card, physicians should read the instructions carefully. They are especially urged to state whether or not they are on extended active duty for the medical reserve corps of the United States Army and Navy. The card should be filled out and returned promptly whether or not a change has occurred in any points on which information is requested. If a change of address occurs before March 1, 1942, it should be reported at once. If any physician fails to receive a card before October 1, he should write at once to the headquarters office stating that fact, and a duplicate card will be mailed.

## NOTES

Three National Scholarships, the outstanding awards to students entering Harvard Medical School this fall, were recently announced by Harvard University. The recipients are Gaston E. Blom, of Tuckahoe, New York, A.B. Colgate University '41; William F. Ketchum, of Evanston, Illinois, A.B. Harvard '41; and Frederick R. Gilmore, of Bloomsburg, Pennsylvania, A.B. Lehigh University '41. This is the fifth year of the medical school's National Scholarship plan, which is similar to that introduced in Harvard College in 1934, and subsequently adopted by the Graduate School of Arts and Sciences, the Graduate School of Design and the Graduate School of Business Administration.

In addition, medical-school scholarships and fellowships totaling \$6,860, for study during the next academic year, were awarded as follows: Matthew and Mary E. Bartlett Scholarship to Harold D. Rosenbaum, of Fair Play, Kentucky; James Jackson Cabot Fellowship to Carl T. Nelson, of Jamaica Plain, Massachusetts; DeLamar student research fellowships to William E. Watts, of Seattle, Washington, Victor C. Vaughan, 3rd, of Richmond, Virginia, and Israel H. Scheinberg, of New York City; Jeffrey Richardson Fellowship to Eugene R. Sullivan, assistant in medicine, Massachusetts General Hospital; George Cheyne Shattuck Memorial Fellowship to Walter E. Knox, of McCook, Nebraska; Charles Eliot Ware Memorial Fellowship to William F. Pollock, of Santa Monica, California; John Ware Memorial Fellowship to Herbert R. Morgan, of Bell, California; Abraham

A. Watson Scholarship to Stuart G. Quan, of Oakland, California; Whitman Fellowship to Henry S. Fuller, of Washington, D. C.; and Dr. William Hunter Workman Scholarship to Ping-Yang Liu, research fellow in bacteriology and immunology, Harvard Medical School.

The Board of Directors of Oglethorpe University has recently announced the opening of a school of medicine, to be located on the university campus, in the suburbs of Atlanta, Georgia. Clinical facilities will be available at the Lawson General Hospital, Grady Hospital and U. S. Veterans' Hospital No. 48. Dr. John L. Jacobs, formerly professor of bacteriology and immunology at Tufts College Medical School, has been elected vice-president of the university in charge of the scientific work of the institution and is now engaged in the organization of courses, admission of students and preparation of classes. Although the school is primarily intended for Georgia residents, anyone may apply for admission.

At the annual meeting of the Massachusetts Board of Registration in Medicine held July 11, 1941, Dr. Francis R. Mahony, of Lowell, was re-elected chairman of the Board and Dr. Stephen Rushmore, of Boston, was re-elected secretary for the ensuing year.

## BOOK REVIEWS

*Criminal Youth and the Borstal System.* By William Healy, M.D., and Benedict S. Alper. 8°, cloth, 251 pp. New York: Commonwealth Fund, 1941. \$1.50.

Since four out of five of the "graduates" of reformatories for delinquents and young criminals commit further offenses on their release, any investigation made by competent scholars on the methods of preventing this human waste ought to be welcomed not only by sociologists and criminologists but by physicians, whose fine tradition in the healing art, tested by time, might well be projected, both civically and professionally, to co-operate in the prevention of crime.

Criminal careers are mainly a problem of youth, and there has been a startling increase of criminality in the 'teen ages. More major crimes are committed at the ages of nineteen and twenty than at any other age. Previous studies have shown reformatories to be dehumanized, depersonalized and regimented—in other words, inefficient. Although improvement in these institutions is not the sole or even the chief means of prevention, anything to improve their administration would help. Accordingly, the Criminal Justice-Youth Committee of the American Law Institute commissioned Dr. Healy, a noted authority on delinquents, and Mr. Alper to make a study of the Borstal system in Great Britain, which, according to the report presented, seems to work quite well.

The authors sketch vividly the organization, personnel and day-to-day life in Borstal and similar institutions, and they give the reader an intimate account of the whole procedure from court commitment to aftercare and parole. The Commonwealth Fund is to be congratulated on the publication of this able, objective and penetrating report.

*Proctology and the General Practitioner.* By Frederick C. Smith, M.D., M.Sc. (med.). 8°, cloth, 466 pp., with 161 illustrations and 5 color plates. Philadelphia: F. A. Davis Company, 1941. \$4.50.

This book, as the name implies, is primarily written for the general practitioner, but it can also be read with benefit by the general surgeon and the proctologist. It

may be divided into three sections diseases of the anus and the anorectal junction, major diseases of the rectum and colon, and parasitic diseases of the entire gastrointestinal tract.

The greater part of the book is devoted to the first section. The chapters on anatomy, anorectal symptoms, history taking, methods of examination, preoperative and postoperative care, choice and methods of anesthesia, and the treatment of hemorrhoids, fistulas, fissures, acute infection and pruritus are comprehensive. Little known to the proctologist is omitted, although some proctologists will not agree with some of the author's conceptions. The most practical features of all these diseases are clearly presented, omitting all unnecessary details and controversial theoretical considerations.

The chapters on major diseases of the rectum and colon, such as cancer, diverticulitis and ulcerative colitis, are very sketchy, being mere outlines.

The chapter on parasitic diseases of the gastrointestinal tract is long and inclusive. It contains very valuable practical information on clinical parasitology, an outstanding feature of the whole book.

The book is written in simple style, the type is large, and the illustrations are adequate. There are numerous witty expressions and rhetorical phrases to distract the reader from the technical monotony. For example, the author refers to cancer of the rectum and sigmoid as 'the wild beast of the jungle, stalking silently on its victim and giving little warning of its approach until it makes its fatal strike'.

The book makes a valuable addition to the library of the general practitioner.

*The Mask of Sanity: An attempt to reinterpret the so-called psychopathic personality* By Hervey Cleckley, B.S., B.A. (Oxon), M.D. 8", cloth, 298 pp. St. Louis: The C. V. Mosby Company, 1941. \$3.00.

This work is, on the whole, as journalistic as the title. Fourteen cases of psychopathic personality are cited, all of them in men, although there are actually as many women who are psychopathic inferiors as there are men. The case histories are given with great fervor and gusto, intermingled with bits of poetry. In fact, the introduction to the book is apparently an original poem, which begins

From chaos shaped, the Bios grows In bone  
And viscus broods the Id And who can say  
Whence Eros comes? Or chart his troubled way?

The reviewer wonders what this has to do with the psychopathic personality.

The vivid description of the cases is followed by an analysis of the literature, together with the introduction of a new name for the psychopathic inferior, 'semicoma dementia', which means a dementia in the understanding of the meaning of life. If that is the disease from which the psychopathic inferior suffers, this term can be applied to most of us, and certainly to the reviewer, since so far as he knows, no one as yet has given us a real insight into the meaning of life. Psychiatry does not need any new names for old subjects, and progress is not recorded in this way.

No essentially new facts are presented. The book is not literary and fictional enough for a novel, yet it has a little too much literariness for a scientific publication. Its merits reside in the earnest interest of the author and

his emphasis on the seriousness of the problem, although he has no real remedy to offer. In point of fact, no one else has.

*Macleod's Physiology in Modern Medicine* Edited by Philip Bard, Ph.D. With the collaboration of Henry C. Bazett, M.D., L.R.C.P., George R. Cowgill, Ph.D., Howard J. Curtis, A.M., Ph.D., Harry Eagle, M.D., Chalmers L. Gemmill, M.D., Magnus I. Gregersen, Ph.D., Roy G. Hoskins, Ph.D., M.D., J. M. D. Olmsted, Ph.D., and Carl F. Schmidt, M.D. Ninth edition. 8", cloth, 1256 pp., with 124 tables and 387 illustrations. St. Louis: The C. V. Mosby Company, 1941. \$10.00.

The tradition of seven editions of this work under the late J. J. R. Macleod, eminent Canadian physiologist, now edited for the second time by Philip Bard, professor of physiology at Johns Hopkins University, makes it the outstanding treatise in this field. It is not intended to be a textbook in applied physiology, as the title implies. Although the original purpose of the book was to serve as a guide to the clinical application of physiology, the present editor and his collaborators, still devoting a great deal of attention to clinical material, deal with it only so far as it illustrates fundamental principles. They assume that the greatest service which physiology can render modern medicine is to continue to solve fundamental problems, even though they may yet not be of immediate practical application.

One may turn to this volume, then, not only as a rich authoritative source book, but as a pathfinder and pace inaker in modern medicine.

*Handbook of Anaesthetics* (Formerly by Ross and Fairlie). Revised by R. J. Minnitt, M.D. (Liverpool), D.A. (D.C.P. & S. Eng.). With chapters on local and spinal anaesthesia by W. Quarry Wood, M.D., Ch.M., F.R.C.S.E. Fifth edition. 12", cloth, 364 pp., with 103 illustrations. Baltimore: Williams and Wilkins Company, 1940. \$4.00.

The fifth edition of this handbook covers the field of anaesthesia quite completely and presents detailed information about the management of the patient under general anaesthesia. The authors have done well to treat the subject, including the physiology of anaesthetics, the preparation of the patient and the techniques of administrations of anaesthetics, so briefly and at the same time to give the reader a working knowledge of the underlying fundamentals.

The anaesthetics are taken up in order, and cover in halothane, intravenous, rectal, local and spinal agents. The author places especial emphasis on ethyl chloride, chloroform, ether and nitrous oxide, since anaesthetists in England still use these more toxic agents. The newer agents and techniques that have been more recently introduced in that country, such as cyclopropane with carbon dioxide absorption anaesthesia, vinylene and the therapeutic use of oxygen, helium and carbon dioxide, are only briefly outlined.

In the section on local and spinal anaesthesia, there is quite a discussion of local agents and techniques and a very brief chapter on spinal anaesthesia.

There are many cuts of apparatus, many of which are different from those used in the United States.

The clinical anaesthetist and the medical student should find this book well worth reading. It gives a clear-cut picture of anaesthesia in England.

Northampton	September 17	Garry deN. Hough, Jr.
Worcester	September 19	John W. O'Meara
Fall River	September 22	Eugene A. McCarthy
Hyannis	September 23	Paul L. Norton

### NEW ENGLAND HOSPITAL FOR WOMEN AND CHILDREN

The monthly clinical conference and meeting of the staff of the New England Hospital for Women and Children will be held on Thursday, September 4, in the classroom of the nurses' residence at 7:15 p.m. Dr. Dorothy K. Scheidell, chairman, will speak on "Occult Kidney Infection."

### EXAMINATIONS FOR APPOINTMENTS IN THE MEDICAL CORPS OF THE UNITED STATES NAVY

Examinations for appointment as assistant surgeon (lieutenant, junior grade), United States Navy Medical Corps, will be held at all the large naval hospitals and the Naval Medical Center, Washington, D. C., on October 6 to 9, inclusive, and January 5 to 9, 1942, inclusive.

Applicants for appointment as assistant surgeon must be citizens of the United States, more than twenty-one but less than thirty-two years of age at the time of acceptance of appointment, and graduates of Class A medical schools who have completed at least one year of intern training in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association.

Examinations for appointment as acting assistant surgeon for intern training in naval hospitals accredited for intern training by the Council on Medical Education and Hospitals of the American Medical Association will also be held on October 6 to 9, inclusive, and January 5 to 9, 1942, inclusive. Applicants for appointment as acting assistant surgeon for intern training must be citizens of the United States, more than twenty-one but less than thirty-two years of age, and members of the junior or senior classes in Class A medical schools. After twelve months of intern training, acting assistant surgeons may apply for appointment as assistant surgeons in the United States Navy.

A circular of information regarding these examinations, physical requirements, rates of pay and promotion

and retirement data may be obtained from the Bureau of Medicine and Surgery, Navy Department, Washington, D. C., on request. Applications for authorization to the examination must be received at the Bureau of Medicine and Surgery three weeks before the examination.

Medical officers of the United States Navy are encouraged to develop a specialty, and are assigned, if they are interested in the specialty warrants such action, to postgraduate instruction in the large naval hospitals, the Naval Medical Center, Washington, D. C., and civilian medical centers. Some of the specialties in which medical officers may seek qualifications are: surgery, medicine, ophthalmology, otolaryngology, roentgenology, laboratory, ology, public health, psychiatry, deep-sea diving, aviation medicine (flight surgery), gas warfare, tropical medicine and medical research and so forth.

### AMERICAN ACADEMY OF OPHTHALMOLOGY AND OTOLARYNGOLOGY

The forty-sixth annual meeting of the American Academy of Ophthalmology and Otolaryngology will be held at the Palmer House, Chicago, October 19 to 23.

The academy's program consists of one general scientific meeting on the morning of the first day, separate programs for the two specialties on alternate afternoons, and instructional courses every morning beginning Tuesday.

During the convention there will be various meetings of small groups, including the "Teacher's Section," societies of local eye, ear, nose and throat societies and other organizations.

Alternating with the scientific programs of the section each afternoon will be an elaborate motion picture program. Thus when the section of ophthalmology meets for formal presentation of papers, motion pictures on otolaryngology will be available for those interested in that field.

## THE TUFTS POSTGRADUATE MEDICAL PROGRAM

SAMUEL PROGER, M.D.\*

BOSTON

**M**OST postgraduate programs in operation today represent an attempt to continue the methods and technics of undergraduate instruction, making only what changes and modifications are required by the fact that the status of the practicing physician differs from that of the undergraduate. Much has been accomplished by this method, but perhaps more might be accomplished if the problem of postgraduate medical education were attacked not only from the standpoint of the school's relation to the practicing physician as a student, but also from the point of view of its relation to his hospital and his patients. Tufts College Medical School has attempted to do this.

In a sense, the problem of postgraduate medical education is the problem of the distribution of better medical care. Just as the fruitful attempt to solve the problem of undergraduate medical education has been largely responsible for the creation in this country of what are probably the world's highest medical standards, so conceivably could a comparably successful solution of the problem of postgraduate medical education assure the widespread utilization of the benefits of these high standards. Much vertical progress has been made, so that today American medicine, at least in its peaks, towers high. On the other hand, horizontal progress has been slow, and it must be admitted that our medical advances can be more widely, more rapidly and more effectively distributed.

Fundamentally, postgraduate medical education is, as the name implies, a union of the academic and clinical aspects of medicine. Logically, therefore, this union can best be maintained through an educational and clinical institution, that is, a medical-school and hospital center. During the last three years an attempt to develop such a fusion for the benefit of practicing physicians has been made by the New England Medical Center, which comprises Tufts College Medical School, the

Boston Dispensary, the Boston Floating Hospital and the Joseph H. Pratt Diagnostic Hospital. This work, so far experimental in nature, has been made possible by the Bingham Associates Fund, of which Dr. George B. Farnsworth is president.

The program has operated through three types of hospitals: the medical-school and hospital center, hospitals in regional centers and small community hospitals. The teaching facilities of each type of hospital are integrated into a single program. The teaching does not emanate from the central source alone. Rather, an attempt has been made to decentralize all activities as much as possible, in the effort to develop every local academic potentiality. Hence, one type of teaching is conducted through the central institution, another through the hospitals in the regional centers, and still another through the small community hospitals.

We have thought of the hospital as an instrument for teaching, regardless of its size or location. As each hospital becomes more of an educational institution, the standard of medical practice within it of necessity rises. This has been a well-nigh universal experience in hospitals that have assumed academic functions. What has been done in the past by medical schools for relatively large hospitals conveniently located to the school, Tufts now hopes to do for hospitals of various sizes, widely separated and distant from the academic center.

There are three general divisions of the program, divisions that to a large extent are interdependent and complementary. They are the Diagnostic Hospital Service, hospital extension services and postgraduate medical courses. Analysis will reveal that these divisions fit into a coherent educational design.

### DIAGNOSTIC HOSPITAL SERVICE

Those fortunate enough to be intimately associated with a teaching hospital are fully aware of the educational advantages of such an associa-

to that which a clinical teacher in a hospital might give a house officer who, following a case work-up, desires advice and instruction. In this manner, the general practitioner in an isolated community may profit educationally from contact with a teaching institution.

A third educational feature consists in pertinent follow-up information. The hospital attempts to keep referring physicians informed of any important developments coming to its attention that may be of benefit to previously referred patients. For example, we have in the last several years seen a number of patients with parkinsonism. These patients were returned to their physicians with a recommendation for treatment by the more or less generally accepted method, with stramonium and scopolamine. Recent articles have appeared reporting good results in the treatment of parkinsonism with the use of the so-called "Bulgarian belladonna." An abstract describing this treatment was therefore sent to each of the physicians who had referred patients with Parkinson's disease. This abstract gave information about the drug and its use, with references to the published reports, for those who wished to obtain further details.

This type of critically filtered information has proved valuable, and it is our intention to extend its use still further, so that the practitioner in an outside community may come to feel almost as though he were on the active staff of the teaching institution.

Through the establishment of such an intimate relation between instruction and the actual care of patients, it is believed that Tufts College Medical School will inevitably increase the scope of its aid to its graduates, as well as to many other general practitioners.

A fourth educational feature of the Diagnostic Hospital Service is the *Bulletin*, which is published every other month and which contains clinical information derived from the various teaching activities at the New England Medical Center, particularly from the daily morning staff conferences at the Joseph H. Pratt Diagnostic Hospital. The *Bulletin* has an unusual appeal in that many of those physicians receiving it have been present at the morning conferences; and this familiarity, one may believe, is not only pleasantly reminiscent but is active in overcoming the customary lack of interest shown by medical men in material of this kind. To those who have attended the morning conferences as undergraduate or postgraduate students, the *Bulletin* represents an educational contact that makes continuous at least

one important phase of a past educational experience.

In addition to the four educational features of the Joseph H. Pratt Diagnostic Hospital listed above, we hope, at a future date, to provide at the New England Medical Center living facilities for those physicians who, through their local community, are in one way or another affiliated with us. Their occasional visits to Boston will thus bring them directly into an academic atmosphere, which should serve as a helpful and pleasant stimulus to their medical interests.

With the anticipated completion of full clinical facilities at the New England Medical Center, the central hospital part of our teaching program can be expected to become much more inclusive, along the lines indicated above.

#### HOSPITAL EXTENSION SERVICES

The hospital extension services are an important and at the same time unorthodox feature of our teaching program. These services are designed to make available improved hospital facilities for medical practice in the various communities concerned. It is clear that a postgraduate program that simply indicates to the general practitioner the value of improved laboratory, x-ray and electrocardiographic facilities, and then leaves him with no opportunity to avail himself of such aids, is not well rounded. A full educational program should take into consideration the hospital in which the physician practices, as well as the physician himself, and the possibilities for educational aid to those members of the hospital staff, non-medical as well as medical, whose services are auxiliary but without which modern medicine cannot be satisfactorily practiced. Such considerations led to the development of the hospital extension services.

These services are co-ordinated through the medical-school and hospital center, the hospitals in the regional centers and the small affiliated hospitals. The small community hospitals have their direct affiliations only with the regional centers, the regional centers being in turn directly affiliated with Tufts College Medical School and the New England Medical Center. At present, regional centers are located in Lewiston (Central Maine General Hospital) and Bangor (Eastern Maine General Hospital). The small hospitals affiliated with the Central Maine General are in Brunswick, Rockland, Bath, Damariscotta, Camden, Skowhegan, Waterville, Augusta, Farmington, Rumford and Boothbay Harbor. Those affiliated with the Eastern Maine General are in Greenville, Dover-Foxcroft, Belfast, Blue Hill, Cas-

tine, Bar Harbor, Machias, Lubec, Calais, Island Falls and Houlton. The plan of working with small hospitals through intermediary centers has proved most satisfactory, as indicated in a previous paper on the subject.\*

Services are now being offered in the fields of pathology, electrocardiography, radiology, laboratory aid, dietetics and library assistance. Briefly, these functions are as follows:

*Pathology.* Since pathology is a highly specialized subject, it is impracticable for physicians to practice part-time pathology as they may, for example, practice radiology. As a result, the small community hospital usually has no local pathologist. Under hospital extension services, all tissue specimens are routinely sent from the small hospitals to the regional-center hospital. An immediate report is sent back, by telephone when necessary, and all questionable specimens are sent on to the head of the Pathology Department at Tufts College Medical School, who is at all times available for consultation. On request, the pathologist in the regional center will gladly review all slides with the interested physician. In an increasing number of cases, furthermore, post-mortem examinations at the affiliated hospitals have been performed by the regional-center pathologist; this is a valuable indication of growing interest on the part of local practitioners. The regional-center pathologist is also available for clinicopathological conferences in the small communities.

*Electrocardiography.* A course of one week's duration in the interpretation of electrocardiograms is given to representatives of the community hospitals. The course is given without charge on the condition that the hospital purchase an electrocardiograph. Then, from the community hospitals, the local electrocardiographer sends a copy of every tracing to the electrocardiographer in the regional center, whose reports become available for check by the physicians in the community hospitals. The tracings that are unusually difficult to interpret are sent from the regional center to Boston, where several well-known cardiologists are available when necessary. In this manner, the small hospitals have available the best authorities on the interpretation of electrocardiograms, when they are needed. At the same time, the electrocardiographer at the small hospital is given constant opportunity for supervision and improvement.

The short course in electrocardiography thus serves as the beginning of a continued and per-

manent form of instruction. This principle is at once one of the most distinctive and most important features of our teaching efforts. Some of the other specialized courses recently given, such as in allergy and hematology, as well as to a large extent the regular courses in general medicine, pediatrics, obstetrics and gynecology, may all be taken as similar examples. This arrangement for postgraduate courses appears to have definite advantages over the customary method of simply offering, to whoever wants it, a course when he wants it. A course that is only an isolated cross-sectional experience in a physician's life is not likely to mean so much to him as one that is a regular part of his active professional career.

*Roentgenology.* Through a recently inaugurated plan, x-ray seminars are held every two weeks at the Eastern Maine General Hospital in Bangor. These are attended by the roentgenologists from the affiliated community hospitals, and traveling expenses are covered by the Bingham Associates Fund. All routine films are sent in advance to the regional hospital, so that consultation notes concerning them will have been dictated and the films of particular interest will have been chosen for discussion at the seminar. Thus, when the men meet, there is discussion of the problems with which they are immediately concerned, and of the general x-ray problems with which they should be kept familiar. This program serves not only as instruction to the doctor but also as a consultation service to the patient, a feature that is likewise significant in the pathological and electrocardiographic services. In addition, it has the advantage of giving the radiologist an opportunity to profit from the experience and material of ten hospitals instead of being limited to his own. In the interval between the seminars, emergency films may be sent in for examination, and the Bangor roentgenologist also makes occasional visits to the local hospitals to help them and to become acquainted with their equipment and facilities. The Bingham Associates Fund makes it possible for the regional radiologist to attend the weekly radiologic seminars at the Massachusetts General Hospital in Boston, which thus becomes, when necessary, a final court of appeal for the small hospitals, serving at the same time as a valuable source of instruction and education to the regional radiologist. The x-ray technicians in the small hospitals meet every second month at the Eastern Maine General Hospital in Bangor for a conference on their own problems. Fellowships for further study in Boston are available for them when needed.

In the Lewiston group, the regional radiologist visits the affiliated hospitals once a week, the pro-

\*Proger, S. The Joseph H. Pratt Diagnostic Hospital. *New Eng. J. Med.* 220:771-779, 1939.

gram otherwise being essentially the same as that of the Bangor group. Of the two, the Bangor plan seems to be more promising, since it is capable of reaching an unlimited number of hospitals in a large area, and geographical factors are minimized.

**Laboratory aid** Scholarships are granted to x-ray and laboratory technicians for advanced and specialized studies, chiefly in the laboratories of the Joseph H. Pratt Diagnostic Hospital. Technicians in each small hospital annually spend one month in Boston for the purpose of improving their technique and learning new methods and procedures. An itinerant technician is provided to substitute in the affiliated hospital for the duration of the course. During the fiscal year 1939-1940, twenty-seven such scholarships for technicians were awarded.

Last winter, in addition, a one-week course in chemistry was given by the chief chemist of the Joseph H. Pratt Diagnostic Hospital at the Central Maine General Hospital for the technicians of the Lewiston group. Attendance at its sessions was large, and demonstrations, appraisals and criticisms of methods were carried out.

In an attempt to standardize laboratory procedures, many of the hospital laboratories receive from the central laboratories solutions of the various reagents used in tests. By means of this arrangement, the number of variable factors is reduced, and accurate results are more easily obtainable in the small community hospitals.

Some of the affiliated hospitals are so small (10 to 20 beds) that they do not seem to require a full-time laboratory technician. No hospital is too small to have nurses, however, and we have therefore arranged for hospitals in this category to send one of their graduate nurses to Boston for a three-month period of instruction in the technique of performing a certain number of simple but important laboratory tests. Through such a course, and annual one-month courses thereafter, it is possible for a graduate nurse to perform, on a part-time basis, common laboratory tests in a small community. Arrangements have been made for the more difficult tests to be done in the regional centers.

**Dietetics** In dietetics, postgraduate study is made possible largely through scholarships, which enable the dietitians in the community hospitals to spend one month of each year regularly at the New England Medical Center, where they are given a continued course of instruction, through which they are kept informed of progress in their field.

**Library assistance** The Gerrish Library at the Central Maine General Hospital serves as a central library for the entire Lewiston group. It prepares bibliographies and sends out books for practitioners, as well as conducting a mailing service on current journals. The affiliated hospitals regularly receive selected current journals by this system. After four days, the journals are sent on to the next hospital, and new ones are received. The plan has received enthusiastic co-operation among the participating hospitals, and many libraries may well envy their record of not one journal lost during the year, although most of the journals have been consulted by many staff doctors.

In addition to these services now being offered, it is hoped that aid may in the future be given in the fields of nursing, anesthesiology and hospital administration.

In summary, then, it is clear that through a system of scholarships and direct hospital consultations a practicable method of continued education in certain auxiliary medical fields has been established. In pathology, instruction is given in the form of consultations and supervision of technical and diagnostic work by the professor of pathology at Tufts College Medical School. In roentgenology, the instruction involves supervision and consultation work by the roentgenologists in the regional centers, who in turn are enabled through a fellowship to attend the weekly seminars at the Massachusetts General Hospital. In laboratory work, the instruction is through annual scholarships for one month's actively supervised work at the New England Medical Center. A similar arrangement obtains in dietetics. In electrocardiography, the instruction in the small communities consists of routine consultations on all tracings, where as for the electrocardiographer in the regional center, instruction through consultation is available when necessary. In general, it is evident that there is opportunity for a free and automatic exchange of opinions between small communities, regional centers and the metropolitan teaching center.

#### *Teaching Ward Rounds*

Another feature of the extension service is aimed directly at the staff members of the affiliated hospitals, namely, teaching ward rounds. It is our belief that the best sort of extramural clinical teaching we can offer practicing physicians is such instruction as may be given through actual contacts with patients, as on ward rounds. Apparently the most satisfactory sort of instruction in general medicine that graduates obtain in their internships is that which they receive from the more or less informal discussions incident to ward rounds and directly related to cases and clinical

problems with which they have intimate association. Since this type of instruction has proved universally effective, it has seemed desirable to apply it in our own work. This we have done, with most encouraging results, by having instructors, chiefly members of our own staff, conduct teaching rounds once a month in the affiliated hospitals. In this manner, we are able to present an informal type of regular instruction that, it is fair to presume, offers much of value, if for no other reason than that it deals with timely and important local problems with which the local men are familiar. An informal discussion by a qualified instructor, in the course of such rounds, on how to treat John Smith (whom most of the local doctors know), who has a bleeding duodenal ulcer, is likely to produce a much stronger impact from the educational point of view than a formal discussion by the same instructor to the same group on the treatment of peptic ulcer.

Correspondence follow-up is applied to this ward-round instruction. The instructor who conducts the rounds sends, within the four weeks following his visit, an informal letter to each of the staff members of the community hospital, presenting some of the recent literature concerning the cases seen on rounds, offering critical comments, and summing up the most important points raised during the visit. In this manner, many of the case discussions on ward rounds are followed up by written instructions. With a different instructor to conduct teaching rounds each month, the staff members of the hospitals concerned receive written or oral instruction almost every other week throughout an academic year (eight or nine months), whereas the individual instructors are not too greatly burdened.

Some of the advantages of instruction through teaching ward rounds are as follows. A natural consequence of the meetings is that the local physicians whose cases are presented are stimulated to improve the quality of their case work-ups. References made to desirable procedures, facilities for which are lacking, in diagnosing or treating the cases under discussion occasionally prompt the staff and hospital to provide for such procedures in the future, thereby improving the entire local apparatus for diagnosis and treatment. A large number of our teaching staff are given an opportunity for intimate contact with most of the staff members of the affiliated hospitals, resulting in a wide diffusion of men and ideas. We are able further to utilize in our teaching program our hospital affiliations. We have the opportunity to offer instruction through what is generally considered the best possible medium, namely, a small

community hospital. We reach most of the physicians in the hospitals concerned. The effectiveness of this instruction is prolonged through the correspondence follow-up.

### POSTGRADUATE COURSES

These courses consist essentially of more or less orthodox short courses in various medical and surgical fields. They vary in duration from one to four weeks and are especially designed for general practitioners. Almost all the courses are given at the New England Medical Center.

Until 1940, only one-month courses were given. There are many reasons why courses of less than one month's duration are undesirable. In fact, even one month is not really long enough for truly adequate instruction in such fields as general medicine, pediatrics, obstetrics and gynecology. However, the more serious objections are avoided if these shorter courses are intended not to serve as complete instruction in any field, regardless of how limited that field, but rather as the beginning of continued instruction.

The advantages of longer periods of instruction are obvious. There are certain real disadvantages. First and foremost is the fact that such courses (one month or more) are at best taken by a relatively small number of physicians in a given area (about 10 per cent, in our own experience as well as in that of others). If by the nature of things only about 10 per cent of the physicians are reached by a given program, the program is automatically limited in its usefulness.

One month is longer than most physicians feel they can safely spend away from their practices. The fact that they can safely spend a month away is not nearly so important as the fact that 90 per cent of the physicians do not believe that they can, or have no desire to devote a month to additional training. The shorter courses would meet the objections at least of some of those who find a month too long.

The principal reasons, then, for instituting one-week courses, after having for three years given only those of one month's duration, may be outlined as follows. A greater number of men may be expected to leave their practices for one week than for one month. In a limited subject, much more concentrated and effective teaching can be given. The students are apt to be more interested in the instruction, since it will be directed toward a subject that they themselves have selected rather than one that covers a general field, many aspects of which may not be of particular interest to them. Experiences throughout the country have indicated that short, intensive courses are, by and

large, more satisfactory than longer ones. The subsequent correspondence, as outlined below, prolongs the effectiveness of such a course.

The courses themselves are, as mentioned above, essentially no different from those given in many schools throughout the country. Two features associated with this part of our teaching program, however, are not widespread and hence deserve some special mention. First, living quarters in the institution are provided for those taking courses. Our efforts have always been directed toward making the postgraduate student throughout his stay with us, and thereafter, if he wishes, an integral part of our organization. The fact that most of these students live with us during their course of study—and will be enabled to do so, we hope, on their repeated visits to Boston subsequently—has tended even further to integrate their work with that of the institution. Throughout their stay, they are constantly in a medical atmosphere, and live and mingle freely with residents, visiting staff and fellow students. This has proved of real value.

The second distinctive feature of this part of our program is the follow-up procedure, whereby physicians who have participated in a course are kept informed by letters from their instructors of new developments in the field covered by the course. These letters are sent out as new material of value to the practicing physician appears in the current literature to which he may not have access, or as new experiences develop that the instructors deem worthy of transmission to the physicians who have participated in their courses.

#### DISCUSSION

In formulating plans for a postgraduate medical program, it may be helpful critically to analyze past programs, many of which, although magnificent in conception, failed to achieve their aims. In these unsuccessful efforts, at least one fact stands out as a possible cause of ultimate failure, namely, that for success they were dependent on the voluntary and active co-operation of the practicing physicians. Widespread voluntary co-operation can be stimulated temporarily by an intensive campaign or it can be maintained locally by a forceful personality, but it cannot be ingrained, so that sooner or later the initial force subsidies, interest wanes, and the program collapses.

Any program, therefore, to be successful on a broad scale must be directed toward the development of a condition in which continual education will be automatic, regular and taken for granted. In other words, active interest and co-operation on the part of the student physician will not be a

prerequisite to initial work, but passive acquiescence alone will be necessary. Perhaps it is not too much to say that the majority of physicians are not interested in continued education when such education requires any undue application or even slight sacrifice. Indifference under such circumstances is unfortunately a widely prevalent human trait, and any program that presumes that higher motives can be made to prevail generally is doomed to failure.

Perhaps this point will indicate, on the other hand, at least some of the factors responsible for the comparatively wide success of undergraduate education. It appears that a fundamental condition in successful educational programs, such as undergraduate programs, is that, to acquire various benefits, certain requirements must be met by the student; and these demand consideration. Study is not made an end in itself, but rather a means to an end, to a definite and to a practically desirable end. Undergraduate educational programs assume that an altruistic goal is not capable of stimulating sustained effort or interest. Hence, we have diplomas, credits, degrees and so forth. These are but artificial and arbitrary goals set up to serve as prolonged stimuli for the production of sustained effort. Students work for four years toward a degree much more conscientiously than they study for enlightenment; they "work for a degree." Some such stimulating force is necessary to overcome normal human inertia, and to be permanently effective it must be permanently active. Why, if artificial stimulation is required for effective undergraduate education, should we assume that the field of postgraduate education can do without it? Actually, there is reason to believe that in older age groups some means is even more necessary for overcoming the human tendency to do nothing that is not required for an obvious and immediately desirable end. Those in the older groups at least have their time otherwise fully occupied.

What we have done has tended to make our teaching program so much a part of a physician's daily life that to some extent it has become automatic and continuous. We have thus far done little in the way of direct inducements. This we hope to do through plans now being developed for more direct affiliations between practicing physicians and the medical school, through the local hospitals, and also through regular opportunities for academic and professional recognition.

#### SUMMARY

The members of the faculty of Tufts College Medical School look on the problem of postgrad-

uate medical education as intimately bound up with the problem of the distribution of better medical care. They have therefore developed a postgraduate medical program that goes beyond the traditional relation of teaching institution to physician, to extend to that physician's hospital and to his patients as well. Thus, although the program includes postgraduate courses for practicing physicians, it is also concerned with improved hospital facilities, as well as diagnostic services, for those physicians, and through them for their patients.

The program functions through the medical school and affiliated hospitals of various sizes (small community hospitals, larger hospitals in regional centers, and the central, medical school and hospital center). What has been done in the past by medical schools for relatively large hos-

pitals conveniently located to the school, it is now hoped can be done for hospitals of various sizes, widely separated and distant from an academic center.

The program is divided into three parts: the Diagnostic Hospital Service, hospital extension services and postgraduate medical courses. In general, the attempt has been made to offer the medical student continued contact with his school throughout his medical career, through the medium of his local hospital and his patients, as well as through the customary postgraduate courses.

The program is so designed as not to interfere with existing educational activities, such as teaching clinics, community and other society meetings, staff meetings, medical-journal reading and so forth; it is intended rather to stimulate and supplement such activities.

## CHLOROSIS\*

ISADORE OLEF, M.D.†

BOSTON

**C**HLOROSIS, defined by Patek and Heath<sup>1</sup> as "a hypochromic anemia in adolescent girls and young women, usually associated with gastrointestinal and menstrual disturbances," is considered today a medical curiosity. In view of its frequency during the latter part of the nineteenth century and its rapid regression since then, "chlorosis seems destined to occupy only a niche in medical history rather than the prominent place among blood dyscrasias which it has held in the past."<sup>2</sup> It is extremely unlikely, however, that a disease etiologically dependent on universally current conditions such as growth, blood loss and inadequate diet should completely disappear. There is no doubt that chlorosis was quite frequent half a century ago. Its high incidence then, however, was more apparent than real. This is obvious from von Hoesslin's<sup>3</sup> critical analysis of 143 cases diagnosed as chlorosis. Of these, 64 had histories suggesting tuberculosis; 25, gastric ulcer; 13, psychoneurosis; 13, secondary anemia due to endocarditis or other infections; and 5, excessive blood loss. The remaining 23 cases might have been called "possible chlorosis." It is true, on the other hand, that chlorosis in severe form is rather uncommon at the present time. One of the factors responsible for the apparent rarity of the disease today is

the allocation of many mild and some severe cases of chlorosis into the categories of nutritional anemia or microcytic anemia with achlorhydria. Among Mills's<sup>4</sup> cases of idiopathic hypochromemia, for example, one twenty-six-year-old patient had been anemic for ten years. In McCann and Dye's<sup>5</sup> series of cases of chlorotic anemia with achlorhydria, one nineteen-year-old woman had been anemic for five years. These were probably cases of adolescent chlorosis.

Chlorosis, therefore, is not so rare today as has been implied. During the last four years, I have personally observed 8 cases. Three of these (Cases 1, 2 and 3) have been reported.<sup>6</sup> There was no clinical or laboratory evidence in any of these patients of acute, recurrent or chronic infections, severe visceral disease or abnormal blood loss.

## CASE REPORTS

**CASE 1.** A 19-year-old girl was seen in November, 1936, complaining of weakness, some shortness of breath, palpitation and vague pains in the lower abdomen. Born in Scotland, she had come to the United States at the age of 2 years. She was born at term and was of normal weight at birth. She received neither orange juice nor cod-liver oil during early infancy. Her appetite had always been capricious, and her diet grossly deficient in green vegetables and meats. At the age of 5, she was told that she was anemic and was given some medicine for the anemia; this she took for a short time. At the age of 10, she was told again by a physician that she was anemic; this time she took the prescribed medicine for about a month. Her

menses had begun at the age of 14 and had always been very scanty, particularly during the previous year.

There was no history of any previous serious illnesses or operations.

On examination, the patient appeared well developed and plump. She had a temperature of 100°F by mouth. The skin was strikingly white, with a suggestion of a greenish tint. The face was definitely puffy. The scleras were not icteric. The mucous membranes of the mouth

CASE 2 A 19 year old girl was first seen by Dr. Frank Mirabello in November, 1936, when she complained of a mild head cold. She was born in Nova Scotia and had been in the United States for 3 years. She was born at term and had normal weight at birth. Her diet had always been adequate. Menstruation began at the age of 13, and the quantity, duration and recurrence of the menses had apparently been normal.

On examination, the patient appeared well developed,

\*The stained blood films of all these cases revealed small pale red cells showing moderate anisocytosis and poikilocytosis. The films of Case 9 presented in add t on some rouleaux formation.

were very pale. The tongue appeared normal. The heart was normal except for a soft systolic murmur over the mitral area. Examination of the lungs, abdomen, pelvis and rectum was negative. The extremities were negative except for some prebital pitting edema. The fingernails appeared rather thin.

The urine and stools were normal. The blood Hinton reaction was negative. The other initial laboratory find

but rather thin. There was slight swelling and reddening of the mucous membranes of the nose, and some generalized injection of the throat. The temperature was normal. There was moderate pallor of the mucous membranes of the mouth. The tongue was normal. The heart, lungs, abdomen and extremities were normal, as were the fingernails.

The urine and stools were normal. The blood Hinton reaction was negative. The remaining initial laboratory findings are given in Table 1, and the results of the gastric analysis are shown in Table 2.

The patient was placed on 4 gr ferrous sulfate therapy thrice daily. At the end of 5 weeks, the red cell count was 5,330,000, and the hemoglobin 82 per cent (Sahl).

CASE 3 This patient, a twin sister of the patient in Case 2, presented a history identical with that given by her sister. She was seen first by Dr. Mirabello in November, 1936, when she complained of a mild upper respiratory infection. On examination, the patient appeared well developed and well nourished. There was slight swelling of the nasal mucous membrane, and slight red dening of the throat. The temperature was normal. There was moderate pallor of the mucous membranes of the mouth. The tongue was normal. Examination of the heart, lungs, abdomen and extremities was negative. The fingernails were normal.

The urine and stools were normal. The blood Hinton reaction was negative. The remaining initial laboratory findings and the results of the gastric analysis are presented in Tables 1 and 2.

Under ferrous sulfate therapy, in doses of 4 gr thrice daily, the red-cell count rose at the end of 5 weeks to 5,400,000, and the hemoglobin to 74 per cent (Sahl).

CASE 4 A 19-year-old American-born Jewish girl was seen in March, 1939, complaining of scanty menstruation. She was born at term and was of normal weight at birth. The past history was not significant. The diet had always been adequate. Menstruation began at the age of 14 and remained regular for 1 year. During the previous 3 years, the menses had been intermittently scanty, more particu

ings are presented in Table 1, and the results of the gastric analysis are shown in Table 2.

The patient was given 4 gr ferrous sulfate thrice daily. At the end of 7 weeks the red-cell count was 4,700,000, and the hemoglobin 82 per cent (Sahl).

The patient felt fairly well for nearly 2 years. The duration and quantity of her menses had remained essentially normal during this period. She was seen again in September, 1938, complaining of fatigue. Physical examination was essentially negative. The urine and stools were normal. The laboratory findings are shown in Table 1, and the results of the gastric analysis in Table 2. The patient was again placed on ferrous sulfate therapy, 4 gr thrice daily. At the end of 6 weeks, the red cell count was 4,250,000, and the hemoglobin 82 per cent (Sahl).

larly during the previous 3 months. For the previous few weeks, the patient had had intermittent headaches. Three years previously, she was treated for a short time with iron for "secondary" anemia.

On examination, the patient appeared well developed, but rather thin. The scleras were not icteric. Examination of the eye grounds was negative. The mucous membranes of the mouth were pale. The tongue appeared normal. Examination of the heart, lungs and abdomen was negative. The fingernails were normal.

The urine and stools were normal. The blood Hinton reaction was negative. The remaining initial laboratory findings and the results of the gastric analysis are presented in Tables 1 and 2.

The patient was given ferrous sulfate, in doses of 4 gr. thrice daily. At the end of 3 weeks, the red-cell count was 4,050,000, and the hemoglobin 82 per cent (Sahli).

CASE 5. A 14-year-old girl was seen in November, 1938, complaining of cramps in one hand. Her parents were Irish. She was born at term and had normal weight at birth. The past history was not significant. Her appetite had always been capricious, and her diet deficient for years in meats and green vegetables. Catamenia began at the age of 14 and had always been irregular and scanty. One year previously, the patient had been treated for a short time with iron for "nutritional anemia."

On examination, the patient appeared fairly well developed but rather thin. There was moderate pallor of the mucous membranes of the mouth. The tongue was normal. Examination of the heart, lungs, abdomen and extremities was negative. The fingernails were normal.

The urine and stools were normal. The blood Hinton reaction was negative. The remaining initial laboratory findings are presented in Table 1, and the results of the gastric analysis are shown in Table 2.

At the end of one month's treatment with ferrous sulfate, in doses of 4 gr. thrice daily, the red-cell count was 4,590,000, and the hemoglobin 80 per cent (Sahli).

CASE 6. A 17-year-old girl was seen in August, 1938, complaining of a sore throat and pain in one knee of 2 days' duration. Her parents were Irish. She was born at term and had normal weight at birth. Her diet had been inadequate for several years in meats and green vegetables. Catamenia began at the age of 12, and the quantity, duration and frequency of the menses had apparently been normal.

The patient had had measles, pertussis, mumps and varicella. She had catarrhal jaundice at the age of 11. She was said to have had rheumatic fever at the age of 4, when she was in bed for 1 week.

Physical examination revealed a well-developed, pale girl. There was a definite greenish tint to the skin. She had an oral temperature of 100.2°F. There was moderate pallor of the mucous membranes of the mouth. The tongue was normal. There was mild generalized injection of the pharynx. The lungs were clear. The heart was normal in size; there was a short systolic mitral murmur. The rest of the examination, including that of the joints, was negative.

Examination of the urine was negative. Examination of the stools revealed a slightly positive reaction with the benzidine reagent on two occasions, but negative reactions on subsequent examinations. Woldman's<sup>7</sup> phenolphthalein test for enteric lesions was negative. X-ray examination of the chest was negative. Electrocardiograms revealed inverted P waves in Leads 2, 3 and 4, a finding that was suggestive of rheumatic heart disease but not of any acute

involvement. The blood Hinton reaction was negative. The remaining initial laboratory findings are shown in Table 1, and the results of the gastric analysis are given in Table 2.

The temperature became normal in a few days and remained so.

In this patient, a therapeutic trial with arsenic was made initially—formerly, arsenic was a popular remedy for the treatment of various anemias; its mode of action, however, still remains obscure. Its effects in this patient were disappointing, as shown in Figure 1. Fol-

FIGURE 1. *The Behavior of the Hemoglobin and the Erythrocyte and Platelet Counts in Case 6 under Arsenic and Iron Therapy.*

lowing the administration of Fowler's solution in gradually increasing therapeutic doses, there was a decrease in the hemoglobin, erythrocyte and platelet values. The most impressive change occurred in the total thrombocyte count, which diminished in a short time almost to the critical level. The subsequent administration of iron, however, in the form of 4 gr. ferrous sulfate thrice daily, produced a satisfactory remission. At the end of 6 weeks, the red-cell count was 4,500,000, and the hemoglobin 85 per cent (Sahli).

CASE 7. A 22-year-old girl was seen in September, 1940, complaining of weakness, dizziness and anorexia of 1 year's duration. Her parents were born in the United States. She was born at term and had normal weight at birth. Her diet had been adequate. Catamenia began at the age of 14 and remained regular until 1 year before examination, when they became somewhat more frequent. There had been no change in the quantity of the menstrual flow. The past history was not significant.

On examination, the patient appeared well developed and well nourished. The mucous membranes of the mouth were pale. The tongue was rather small and slightly atrophic. Examination of the heart, lungs, abdomen and extremities was negative. The fingernails were normal.

Examination of the urine revealed the slightest possible

physician for observation because of unexplained anemia. His parents were of French-Canadian origin. He was born at term and was of normal weight at birth. His diet had been adequate. There was no history of any serious illnesses in the past.

Physical examination revealed a very well developed and well nourished boy. He had an oral temperature of

FIGURE 2 The Behavior of the Hemoglobin and the Erythrocyte and Platelet Counts in Case 1 under Iron Therapy

trace of albumin on one occasion. Renal function tests were negative, and the stools were normal. The blood Hinton reaction was negative. X-ray study of the chest was negative. The remaining initial laboratory findings are presented in Table 1, and the results of the gastric analysis are shown in Table 2.

The patient was given 4 gr ferrous sulfate thrice daily. At the end of 8 weeks, the red-cell count was 4,800,000, and the hemoglobin 87 per cent (Sahli).

CASE 8 A 16-year-old boy was seen in October, 1940. He had no complaints, and was referred by his school

100°F. There was a definite greenish tint to the skin, and a marked pallor of the mucous membranes of the mouth. The tongue was rather large and smooth. There was a loud systolic murmur over the mitral and pulmonic areas. The fingernails were thin, brittle, flattened and spooned.

The first urine examination showed a very slight trace of albumin, but subsequent examinations were negative. The first stool examination showed a slightly positive reaction with benzidine reagent, but subsequent examinations were negative. X-ray studies of the chest and the gastrointestinal tract were negative. Electrocardiograms

were normal. The blood Hinton reaction was negative. GastrosCOPY performed by Dr. Henry H. Lerner revealed evidence of acute and chronic gastritis. The other initial laboratory findings are shown in Table 1, and the results of the gastric analysis are presented in Table 2.

The patient was given 4 gr. ferrous sulfate four times daily. This was increased at the end of a week to six doses a day. At the end of 8 weeks, the red-cell count was 4,945,000, and the hemoglobin 85 per cent (Sahli).

### DISCUSSION

The anemia of patients with chlorosis is of the hypochromic microcytic type. The erythrocytes are flattened, small in size and poor in hemoglobin. An important and striking hematologic feature is thrombocytosis, which is not frequent, but which, when encountered, may be very marked. When thrombocytosis is present, the platelets undergo unusual quantitative changes after the institution of iron therapy. This behavior of the platelets is unique and very different from their behavior in other types of anemia under treatment, as I have pointed out elsewhere.<sup>6</sup> This is illustrated by Figure 2, which presents the hemoglobin levels and erythrocyte and platelet counts in Case 1. In November, 1936, the initial platelet count was 2,671,000 (normal count about 500,000<sup>8</sup>). Under iron therapy, the total thrombocyte count dropped promptly to approximately the normal level as the hemoglobin became elevated. Medication was discontinued at the end of about two months. When the patient was seen again in September, 1938, the platelet count was 700,000, and the hemoglobin 71 per cent (Sahli). The patient was obviously in mild relapse. Under iron medication, the platelet count again decreased to about the normal level as the hemoglobin values became elevated. The behavior of the thrombocytes in 1938, when the patient was in relapse, was the same, though not so spectacular, as in 1936. This inverse relation of the platelet values and hemoglobin levels represents an unusual hematologic finding. These quantitative changes in the platelets undoubtedly play a significant role in the development of the spontaneous venous thrombosis that is, at times, observed in these patients.

#### *Gastric Acidity*

Textbooks of medicine describe chlorosis as an anemia usually associated with either normal or increased acidity of the gastric contents. Many investigators, Naegeli<sup>9</sup> and Witts<sup>10</sup> among others, differentiate chlorosis from primary hypochromic anemia on the basis of the degree of the gastric acidity: in chlorosis, there is said to be an abundance of acid secretion in the stomach, and in primary hypochromic anemia there is usually an acidity. In

the literature, however, one finds an array of most conflicting reports describing isosecretory, hypersecretory and hyposecretory types. The most comprehensive report is that of Arneth,<sup>11</sup> who examined the gastric contents of 23 patients with chlorosis and found the total acid levels to be either normal or increased. However, careful analysis of the cases reported by this author reveals that the diagnosis of chlorosis can be seriously questioned in a number of cases. At least 5 of the patients had diseases that by themselves could produce anemia or could easily aggravate considerably a pre-existing anemia. Arneth's levels for the total acidity after a test meal ranged between 0.15 and 0.25 per cent in normal persons, and between 0.15 and 0.38 per cent in patients with chlorosis. At the present time, the normal ranges for gastric acidity are given as 0.4 to 0.5 per cent for free hydrochloric acid, and 0.4 to 0.6 per cent for the total acidity (Levinson and MacFate,<sup>12</sup> Wright<sup>13</sup> and Müller and Seifert<sup>14</sup>). Despite the fact that Arneth employed laboratory methods quite similar to those used now, the results he obtained were certainly low when compared with present standards. Considered from this angle, all his patients had hypochlorhydria. Furthermore, Arneth determined only the total acidity. In analyzing the gastric contents, it is essential to determine both free and total acidity. Decrease or absence of free hydrochloric acid is usually associated with a decrease in the total acidity and is indicative of either functional or organic disease of the parietal or oxyntic cells in the stomach. This type of deficiency assumes considerable significance in certain types of anemia, more particularly in pernicious anemia, primary hypochromic anemia, nutritional anemia in children and chlorosis.

Patek and Heath<sup>1</sup> were the first to carry out gastric analyses with histamine on patients with chlorosis. Of the 4 cases they reported, 1 patient had normal gastric acidity, 1 had marked hypochlorhydria, and 2 had complete achlorhydria. In other words, 50 per cent of their patients had complete histamine achlorhydria, and 25 per cent histamine hypochlorhydria. Of the 8 cases herein reported (Table 2), 4 had total histamine achlorhydria, 2 had hypochlorhydria after the injection of histamine, 1 had achlorhydria after a test meal, and 1 had hypochlorhydria after a test meal and normal acidity after the injection of histamine. In this latter group, therefore, 50 per cent of the patients had complete histamine an acidity, and 25 per cent had histamine hyp acidity.

The frequency of true histamine an acidity in normal adults is 10.8 per cent (Bloomfield and

Polland<sup>15</sup>). A review of the literature discloses that achlorhydria, even after the injection of histamine, is rather common among the very young (Klump and Neale,<sup>16</sup> Neale,<sup>17</sup> Vanzant et al<sup>18</sup> and Cutter<sup>19</sup>), then decreases rapidly in frequency, and remains low in incidence until about the age of twenty years. Between the ages of fifteen and twenty the incidence is very low (Vanzant et al,<sup>18</sup> 2.8 per cent; Wright,<sup>20</sup> 1.2 per cent; Bockus et al,<sup>21</sup> none; Polland and Bloomfield,<sup>22</sup> none). In other words, during the age periods when chlorosis is usually encountered, achlorhydria is rare. Therefore, the high incidence of histamine

of hemoglobin at a maximal rate than cases of hypochromic anemia without achlorhydria do. He also noted that small doses of iron often have essentially no effect in the achlorhydric patient, but frequently can cause a definite hemoglobin increase when the gastric acidity is about normal. Achlorhydria therefore reflects an abnormal state in the gastrointestinal tract that interferes with the liberation and absorption of the dietary iron and leads to a depletion of the iron stores in the body. As the demands on the hemoglobin and iron stores become increased, anemia appears. In chlorosis these new demands are due chiefly to

TABLE 3 Differential Features between Chlorosis and Primary Hypochromic Anemia

FEATURE	CHLOROSIS	PRIMARY HYPCHROMIC ANEMIA
Age	14 to 40 years	Usually 30 to 40 years
Symptoms	Those of anemia and of gastrointestinal and menstrual disturbances	In addition to those of anemia: sore tongue, dysphagia (Plummer-Vinson syndrome), paronychia and dermatitis
Skin	Texture normal; may present chlorotic or greenish tint; amount of pigmentation may be very scanty	Often dry and inelastic; may present abnormal pigmentation frequently fissures at the angles of the mouth
Hair	Normal	Frequently dry and prematurely gray
Fingernails	Usually normal	Frequently brittle, flattened, grooved and spooned
Tongue	Usually normal	Frequently atrophic
Splenomegaly	Rare; slight splenomegaly in 10 per cent of cases <sup>18</sup>	Frequent (in 50 per cent of cases <sup>23</sup> )
Blood	Leukocytes normal; occasionally increased; platelets normal; occasionally greatly decreased	Leukocytes normal or reduced; platelets usually reduced; occasionally normal <sup>24</sup>
Bone marrow	Normal <sup>14</sup> or hyperplastic <sup>14</sup>	Normoblastic hyperplasia <sup>25</sup>
Spontaneous venous thrombosis	In 2 to 3 per cent of cases <sup>18</sup>	None
Course	Remission without treatment; with permanent cure common	Spontaneous remissions rare

hypochlorhydria and achlorhydria found in patients with chlorosis must be considered one of the most characteristic features of this disease.

The free hydrochloric acid normally present in the stomach apparently affects ingested iron in two ways: it aids in the ionization of iron, and it prevents the formation of insoluble and undissociated iron compounds, particularly ferrous phosphate. The defective gastric secretion of the type observed in chlorosis must, therefore, play a role of some significance in the development of an iron-deficiency state. There is considerable evidence in favor of this view. Thus, Mettner and Minor<sup>23</sup> have shown that iron is more potent for blood formation when absorbed from an acid medium within the intestinal tract, rather than from an alkaline medium. Kellogg and Mettner<sup>24</sup> have observed that in some anemias due to chronic blood loss from peptic ulcer the alkalization process associated with a Sippy regimen inhibits the absorption of iron contained in the food. The iron balance studies of Fowler and Brer<sup>25</sup> indicate that achlorhydria interferes with the absorption of iron. Minor<sup>26</sup> has observed that cases of idiopathic hypochromic anemia with achlorhydria usually require distinctly larger doses of iron for the regeneration

growth and menstruation (Heath and Patek,<sup>1</sup> 27 Heath<sup>28</sup>). According to this hypothesis, chlorosis is a deficiency disease conditioned in many cases by a disorder of the gastrointestinal tract.

Since the growth factor is equally operative in both sexes, one would expect to find occasional cases of chlorosis among males. Allbutt<sup>29</sup> and, more recently, Witts<sup>30</sup> have described the disease in the male sex. The latter investigator reported 5 cases; the diagnosis in 2 cases, however, is doubtful. Case 8 of the series reported here represents a striking case of male chlorosis.

### Differential Diagnosis

There has been considerable diversity of opinion regarding the possible relation between classic adolescent chlorosis, summarized recently by Heath,<sup>28</sup> 32 and primary hypochromic anemia (also called "idiopathic hypochromic anemia," "simple achlorhydric anemia," "cryptogenic achylie chlor anemia," "chronic chlorosis" and hypochromic gastrogenous anemia), first clearly defined by Faber<sup>32</sup> and described more recently in detail by Heath and Patek,<sup>27</sup> Witts,<sup>33</sup> Dameshek,<sup>34</sup> Minor<sup>35</sup> and Wintrobe and Beebe.<sup>36</sup> Thus, Naegeli<sup>3</sup> and Witts<sup>30</sup> are of the opinion that, in the absence of

achlorhydria and dysphagia, the microcytic hypochromic anemia of middle-aged women is allied to adolescent chlorosis. Heilmeyer<sup>37</sup> believes that of the two primary iron-deficiency states, *chlorosis* and primary hypochromic anemia, the former is associated with atony of the stomach and ptosis leading to defective iron absorption, and the latter with a chronic change in the gastrointestinal tract. Adamson and Smith<sup>38</sup> and Bloomfield<sup>39</sup> maintain that chlorosis and primary hypochromic anemia are the same disease. Of course, it is possible that the clinical picture of chlorosis has been altered and that the relatively recently recognized syndrome called "primary hypochromic anemia" is really not a new type of anemia, but rather an example of modified chlorosis. In fact, some authors do speak of present-day or latter-day chlorosis (Mills,<sup>40</sup> Schulten<sup>41</sup>). It seems to me, however, more reasonable to consider chlorosis as a definite disease entity, a view entertained by many observers, Heath and Patek<sup>1, 27, 28, 31</sup> and Minot<sup>35</sup> among others. It occurs in two forms, a severe one, which is rather infrequent, and a mild one, which is, according to Heath and Patek<sup>27, 28, 31</sup> and Davidson, Fullerton and Campbell,<sup>42</sup> quite common. It presents a number of characteristic features differentiating it from primary hypochromic anemia, as shown in Table 3. It must be admitted that atypical cases of both conditions are occasionally encountered that seem indistinguishable.

#### SUMMARY AND CONCLUSIONS

Classic adolescent chlorosis has not disappeared; and since histamine anacidity or hypoacidity is a common finding, it is probably a deficiency disease conditioned by a disorder of the gastrointestinal tract. In chlorosis, the red cells are hypochromic, small and flattened. The thrombocytes quantitatively are normal or increased. In other types of anemia, such as pernicious anemia, primary hypochromic anemia and anemia due to acute and chronic blood loss, the number of platelets is reduced and rises with improvement of the anemia. In chlorosis, on the other hand, there is an inverse relation between the platelet level (when elevated above normal) and the hemoglobin value. When the thrombocytosis is marked, it is a very significant, if not an essential, factor in the production of spontaneous venous thrombosis at times observed in these patients. Iron therapy cures the disease.

The term "chlorosis" should be discarded. The disease is more appropriately called "hypochromic iron-deficiency anemia of adolescence, frequently associated with achlorhydria."

## IMPERFORATE HYMEN WITH HEMATOCOLPOS\*

STANLEY O HOERR, M D †

BOSTON

**I**MPERFORATE hymen with hematocolpos, an infrequently encountered condition, may present difficulty in diagnosis and is not without danger in treatment.<sup>1-3</sup> In 1939, Tompkins<sup>4</sup> collected 113 cases from the literature and noted that there had been deaths in 6 cases and severe pelvic infections in 9; he added 5 cases, with a single fatality and an additional case of pelvic infection. It is the purpose of this paper to add to the literature 7 cases seen and treated at the Peter Bent Brigham Hospital from 1914 through 1940, certain diagnostic and therapeutic features are re-emphasized

### CASE REPORTS

**CASE 1** R. S., an 18-year-old girl, was admitted on December 4, 1914, complaining of back pain of 6 months' duration. Although the patient had been married for 5 months, coitus had never been successful. She had never menstruated. For 2 months, the pain had become severe, and was noted in the lower abdomen. She had had several bouts of urinary retention lasting 1 or 2 days.

Examination showed a young woman with well developed secondary sexual characteristics. There was a slightly rounded, tender, fluctuant, lower abdominal mass rising just above the umbilicus. The hymen was imperforate and bulging, and carried an impulse from the abdominal mass. By rectum, a vaginal mass was palpable.

At operation, the hymen was incised under ether anesthesia, and approximately 750 cc of reddish brown, viscid fluid evacuated. This was not cultured. A small uterus and normal vaults were palpated. The patient was afebrile after operation, and was discharged on the 7th postoperative day.

Three years later, in 1917, the patient was seen in the Outdoor Department. She reported normal periods, and had borne a child 1½ years previously.

**Comment** A normal pregnancy took place in a patient whose treatment was long delayed.

**CASE 2** H. H., a 14-year-old girl, was admitted on August 21, 1931, complaining of intermittent lower abdominal pain of 2 years' duration. The attacks came at approximately monthly intervals and lasted 5 to 7 days.

\*From the Surgical Service, Peter Bent Brigham Hospital.  
†Instructor in surgery Harvard Medical School, resident surgeon, Peter Bent Brigham Hospital.

the pain included the lower back. She had never menstruated, nor had she had any urinary symptoms.

Examination showed a slightly obese young girl with normal secondary sexual development. There was an indefinite, slightly tender, midline, lower abdominal mass. The hymen was imperforate. By rectum, a large fluctuant mass was palpable.

At operation, the hymen was excised under ether anesthesia, and a large amount of thick, "mucinous" old blood released. Culture was negative. The patient was afebrile after operation and was discharged on the 15th postoperative day.

Six months later, an examination in the Outdoor Department showed her to have a small normal uterus and cervix. In January, 1941, 9 years later, she reported normal and regular menstruation, although married for 1½ years, she had not become pregnant.

**Comment** A return of normal function followed drainage.

**CASE 3** R. J., a 13-year-old girl, was admitted on November 10, 1937. For about 4 months, she had noted increasing abdominal distention, and for 2 months she had had some lower abdominal pain, chiefly in the right lower quadrant. During this period, she had also experienced some difficulty in starting urination. She had never menstruated.

Examination showed a well developed young girl with normal secondary sexual characteristics. There was a fluctuant, lower abdominal, midline tumor resembling an overdistended bladder, but persisting after catheterization. The hymen was imperforate and bulged slightly when pressure was exerted on the abdominal mass. By rectum, a transmitted fluid wave from the abdominal mass could be palpated, but there was not a marked bulging of the vagina.

At operation, the hymen was incised under ether anesthesia, and 900 cc of chocolate-colored viscid fluid evacuated. The vagina was irrigated with saline. Culture of the fluid was negative. The patient was placed on constant urethral drainage for 6 days, remained afebrile, and was discharged on the 9th postoperative day. A questionable nodule of cervix was the only portion of the internal genitalia that could be palpated.

Following operation, the patient never established a normal menstrual cycle, although her sexual development was in other respects normal. Her periods were scant and irregular, with intervals of amenorrhea lasting as long as 4 months. The flow was usually "watery" blood lasting only a few hours, although recently (December, 1940) she

had a 3-day flow with clots. A course of injections with one of the anterior pituitarylike hormones had no appreciable effect. The patient also suffered from vague abdominal pain, chiefly in the flank; this could never be explained, even after several readmissions for study, and a complete urologic investigation.

**Comment.** This patient may still develop a normal menstrual cycle; if not, one must suppose that the uterus was so damaged that it is incapable of normal menses. There is no evidence that the ovaries do not function.

**CASE 4.** N.G., an 11-year-old girl, was admitted on July 7, 1938. This patient, one of twins, had had a foul-smelling vaginal discharge for several weeks. Her twin sister had had 3 normal menstrual periods, whereas she had had none. There had been no abdominal pain or urinary symptoms.

Examination showed a well-developed young girl with normally developed secondary sexual characteristics. The abdomen was normal. The hymen was imperforate except for a pin-point opening just beneath the urethral orifice, from which pus could be expressed by pressure through the rectum. Fullness in the vagina was palpable by rectum.

Under ether anesthesia, a thick hymen was incised and a pint of thick, foul-smelling pus evacuated. The vagina was irrigated with saline. Culture of the pus yielded a mixed growth of *Staphylococcus aureus*, *Streptococcus hemolyticus* and *Escherichia coli*. A normal-sized uterus and normal vaults could be palpated. The patient was discharged, afebrile, on the 1st postoperative day, to receive vaginal irrigations and protargol suppositories at home.

Follow-up in January, 1941, 2½ years later, revealed that the patient was having regular, painless periods lasting 4 days.

**Comment.** The problem presented by this patient differed from that in the usual case, inasmuch as infection from below had taken place. Local immunity was already well established, and the treatment became that of any well-localized abscess. There was no need for a long hospital stay, and vaginal irrigations had a definite usefulness.

**CASE 5.** M.R., a 14-year-old girl, was admitted on August 30, 1939. For 3 days, she had had pain in the rectum, and for 2 days she had had progressively severe lower abdominal pain. She had never menstruated.

Examination showed a well-developed young girl. There was a tender suprapubic mass rising halfway to the umbilicus. The hymen was imperforate, thin and bulging. A tender, boggy mass was palpable anteriorly by rectum.

Without anesthesia, but with careful preparation of the vulva, the hymen was incised in the Outdoor Department, and 450 cc. of dark blood released. This was not cultured. The patient was admitted to the hospital for observation, and was discharged 36 hours later.

Four weeks later, a normal-sized uterus could be palpated by rectum. In February, 1941, about 18 months after operation, the patient reported periods occurring regularly every 28 to 30 days, lasting 4 to 7 days, and occasionally accompanied by lower abdominal pain.

**Comment.** The intern who cared for this patient evidently had no understanding of the potential dangers to which he was subjecting her. It was fortunate that there was no postoperative infection. A normal menstrual cycle resulted after drainage.

**CASE 6.** M.N., a 15-year-old girl, was admitted on February 22, 1940, complaining of increasingly severe lower abdominal pain of 4 days' duration. She had never menstruated or had any urinary symptoms.

Examination showed a thin, young girl with normal secondary sexual development. There was a soft, rather tender, lower abdominal mass rising halfway to the umbilicus. The hymen was imperforate and bulging. By rectum, a tender mass was felt anteriorly.

At operation under ether anesthesia, the hymen was excised and 1000 cc. of chocolate-brown old blood evacuated. Culture of this was negative. A small normal uterus and normal vaults were palpated. The patient remained afebrile after operation and was discharged on the 11th postoperative day.

In September, 1940, 6 months after operation, she reported regular, normal, painless periods lasting 6 days. Examination showed that the hymenal opening had contracted to a size of 5 mm.

**Comment.** A return of normal function followed drainage. The introitus requires further surgical opening, in spite of the supposed excision of the hymen at the time of operation.

**CASE 7.** M.L., a 15-year-old girl, was admitted on August 9, 1940, complaining of constipation, back pain and aching down the anterior thighs for the preceding 7 months. She had never menstruated or had any urinary symptoms.

Examination showed a thin young girl with normal secondary sexual development. The abdomen was normal. The hymen was imperforate and bulging. An anterior mass was palpable by rectum.

Under gas-oxygen anesthesia the hymen was incised and 500 cc. of chocolate-colored thick fluid with some clots evacuated. *Bacillus subtilis* was cultured from this, but was regarded as a contaminant. No uterus or masses could be palpated. After operation, the patient remained afebrile and was discharged on the 10th postoperative day.

Five months after operation (January, 1941), she was seen in the Outdoor Department. A small uterus could be palpated by rectum. The hymenal opening was small. The patient reported regular, normal, painless periods every 28 to 30 days.

**Comment.** A return of normal function followed drainage.

### SYMPTOMS, SIGNS AND DIAGNOSIS

Imperforate hymen with hematocolpos occurs in girls between the ages of eleven and eighteen years. The symptoms are a direct result of the accumulation of menstrual blood behind the imperforate hymen. An invariable feature of the history is the fact that the patient has never menstruated; yet, curiously, although understandably, this all-important information is rarely volunteered and is never a prominent symptom. The usual presenting complaint is lower abdominal pain, which is commonly associated with pain in the lower back and occasionally in the rectum or anterior thighs. The pain is often crampy and may be severe. It may occur at intervals corresponding to the time of the presumed menstrual periods (Case 2). As shown in Table 1, abdominal pain was a presenting symptom in 5 of

the cases reported in this paper, although in one (Case 1) pain in the back and in another (Case 5) pain in the rectum seemed equally important. It is noteworthy that although all 5 of these patients had an easily palpable abdominal mass, not one had apparently attached any significance to it, even if she had noticed it.

Difficult urination or even complete urinary retention frequently occurs in these cases.<sup>1</sup> Only

patients should be hospitalized both for the operative procedure and for a postoperative period of ten to fourteen days. The operation must be carried out with scrupulous asepsis. Simple but generous incision of the bulging hymen may be sufficient, but if the hymen is thick and tough, excision may be preferable. A careful irrigation of the vagina in the operating room is probably without danger, but irrigations and douches must

TABLE 1 Summary of 7 Cases of Imperforate Hymen with Hematocolpos

CASE NO	AGE	DURATION OF SYMPTOMS	ABDOMINAL PAIN	COMPLAINTS BACKACHE	DIFFICULT URINATION	ABDOMINAL MASS	RESULT†
1	18	6 months	Yes	Yes	Yes	Yes	Normal menses pregnancy

\*The only complaint was a foul vaginal discharge.

†All cases treated by incision or excision of the hymen.

2 of the reported patients (Cases 1 and 3), had urinary symptoms, and in neither were they prominent.

A careful physical examination cannot fail to establish the diagnosis. If a vaginal and rectal examination is invariably performed on girls or young women complaining of abdominal pain or difficult urination, cases of imperforate hymen with hematocolpos will not be overlooked, and cases in which the diagnosis is made only after laparotomy for real or supposed appendicitis,<sup>2,3</sup> or after cystoscopy,<sup>4</sup> will be prevented. It is unfortunate that in this age group the physician most easily persuades himself that such an examination is undesirable and probably unnecessary. In most cases, there will be a visible bulge at the introitus. An error may be made in regarding a small normal hymenal orifice as imperforate if it is concealed by overlying folds of mucosa, but a probe will demonstrate an opening if present. By rectum, the blood-filled vagina will be felt anteriorly as a boggy mass. There will usually be a slightly tender, rounded, lower abdominal midline mass, contiguous with the vaginal mass.

#### TREATMENT

The treatment consists in surgical drainage through the vagina of the dammed-up menstrual secretions. These patients, however, are particularly susceptible to ascending infection, introduced from without, which may produce a fatal pelvic cellulitis or peritonitis. Such an infection may have its onset days or even weeks after surgical drainage, as shown by reported cases. Because of this special danger from sepsis, these

not be used in the postoperative period. After the fluid has been evacuated and while the patient is still under anesthesia, a rectal, rather than vaginal, examination should be performed to determine the presence of palpable adnexal masses. If such masses are found, an immediate exploratory laparotomy should be considered, as suggested by Tompkins,<sup>1</sup> to remove or drain the blood-distended tubes.

In the postoperative period, the points to be stressed are bed rest in Fowler's position and the maintenance of strict perineal cleanliness. Some surgeons advocate a constipating regime for four or five days, although this does not appear to be necessary. A short course of sulfanilamide as a prophylactic is worthy of consideration. No restrictions on patients are required, once the period of hospitalization is over. Nevertheless, it is sound practice to advise against douching, tub bathing or vaginal examinations until two menstrual periods have passed, as urged by Tompkins.<sup>1</sup>

#### PROGNOSIS

The possibility of a fatal ascending infection has been pointed out; this should be avoidable with the exercise of sufficient care. Most of these patients start a normal menstrual cycle, and some go on to child bearing. The oldest patient (Case 1) in this group, aged eighteen, in whom one would naturally expect the severest damage to the uterus and tubes, bore a child eighteen months after operation. On the other hand, another patient (Case 3), aged thirteen at operation, subsequently had irregular and very scanty periods. One should neither be too pessimistic

with the late case, nor promise too much with the early one.

### SUMMARY

Imperforate hymen with hematocolpos is a syndrome occurring in girls between the ages of eleven and eighteen who have never menstruated. The usual presenting symptom is abdominal pain, often associated with back pain. There may be a history of difficulty in urination. The diagnosis is established by demonstrating the imperforate hymen, which is often bulging, and by palpating the blood-filled vagina through the rectum. There is usually an associated suprapubic mass.

Treatment consists of vaginal drainage of the dammed-up blood by incision or excision of the hymen under the most scrupulous asepsis; if adnexal masses persist after drainage, an immediate laparotomy for further surgical treatment of the tubes must be considered. The postoperative regimen consists of rest in bed in Fowler's

position for ten to fourteen days, strict perineal cleanliness and postponement of douches, tub baths and vaginal examination until several menstrual periods have passed. The prognosis for a normal menstrual cycle is good; normal pregnancies are known to occur.

Seven cases seen and treated in the Surgical Service of the Peter Bent Brigham Hospital from 1914 through 1940 are reported. There were no postoperative infections in this group, and no deaths. One patient is known to have had a subsequent normal pregnancy.

## THE SIGNIFICANCE OF A HISTORY OF ASTHMA WITH REFERENCE TO SEROTHERAPY\*

DAVID D. RUTSTEIN, M.D.,† EDWARD S. ROGERS, M.D.,‡ AND  
ISABEL McCaffrey, A.B.§

ALBANY, NEW YORK

A RECENT circular letter<sup>1</sup> prepared by the Committee on Chemotherapeutic and Other Agents and the Subcommittee on Infectious Diseases, of the Division of Medical Sciences, National Research Council, included a discussion of the contraindications to the use of serum in patients with a history of allergic manifestations. The circular letter stated, "Serum should never be given to patients who have a history of asthma of any type or to those who have a history of hay fever." Because the circular letter carries the weight of authority, the statements contained in it are likely to influence treatment of the civilian population, as well as that of members of the armed forces. Since the sentence quoted was at variance with the impression gained from a previous study of reports on the use of antipneumococcus horse serum in New York State, it was considered appropriate to subject these reports to careful analysis regarding the point at issue. This seemed particularly im-

portant because a thorough review of the literature concerning immediate serum reactions in man failed to reveal any study comparing the incidence of immediate serum reactions in patients with and without a history of asthma.

In the review of the literature, no case of a death associated with a reaction to antipneumococcus horse serum in an asthmatic patient was found. Bullova<sup>2</sup> reported 8 fatal cases following the injection of antipneumococcus horse serum, none of which had a preceding history of asthma, and Heffron<sup>3</sup> reported 2 fatal cases, neither of which had a history of allergy preceding the injection of the serum. Heffron<sup>4</sup> also reported, "In the course of the Pneumonia Study and Continuing Program in Massachusetts, at least 15 patients with a history of asthma and 2 with a history of hay fever were treated without unfavorable reactions."

Between January 1, 1937, and March 31, 1939, 3215 reports on the use of antipneumococcus horse serum in which information of the history of allergy was recorded were received by the New York State Department of Health. Of these, 101 (3.1 per cent) indicated a history of asthma, although

§Assistant statistician, New York State Department of Health.

in no case was the asthma related to a history of specific sensitivity to horse emanations. This study must not be interpreted to include patients with a history of specific sensitivity to the animal from which the serum was derived.

As shown in Table 1, the incidence of immediate

\*Adjusted to allow for older age distribution in cases with history of asthma.

serum reactions in the patients with asthmatic histories was greater (45.5 per cent) than that in those without such histories (29.6 per cent). This difference was found to be most significant in those patients having the anaphylactic type of reaction. However, the incidence of fatal reactions

TABLE 2. Incidence of Fatal Reactions Among Pneumonia Patients Treated with Specific Antipneumococcus Horse Serum, according to History of Asthma

GROUP	NO OF CASES	FATAL REACTIONS
Cases with history of asthma	101	1† (1.0%)
Cases with no history of asthma	3114	22 (0.7%)
Total	3215	23 (0.7%)

†This patient was sixty-five years of age with a long-standing history of cardiovascular disease and a three-year history of asthma. The conjunctival and intradermal tests were negative and he received 1 cc of serum intravenously without reaction prior to the fatal dose. The reaction was circulatory in nature.

was approximately the same in both groups of patients (Table 2). These data suggest caution

In a study recently published elsewhere<sup>8</sup> of 25 patients with fatal serum reactions and 790 with nonfatal immediate serum reactions of all degrees of severity, it was shown that immediate reactions following the injection of antipneumococcus horse serum can be divided into four categories: thermal, anaphylactic, circulatory and miscellaneous, the clinical pictures of which are defined. In that study all but one of the fatal serum reactions were shown to be circulatory in nature and not related to recognizable protein hypersensitivity.

in the administration of serum to asthmatic patients, but do not appear to justify the prohibition of its use in those patients with asthma not related to specific animal protein sensitivity.<sup>8</sup>

Further evaluation of the importance of asthma can be derived from a study of the fatality rates of serum-treated pneumonia patients according to asthmatic status. The fatality rates of patients with and without asthmatic histories did not significantly differ from each other after correction for differences in age and bacteremia (Table 3).

TABLE 3. Case Fatality Rates Among Pneumonia Patients Treated with Specific Antipneumococcus Horse Serum, according to Incidence of Reactions and History of Asthma

GROUP	HISTORY OF ASTHMA		NO HISTORY OF ASTHMA	
	NO OF CASES	% OF DEATHS	NO OF CASES	% OF DEATHS
Cases with reaction	46	12 (17.5%)	922	1.8 (13.9%)
Cases with no reaction	51	15 (14.4%)	2102	318 (15.1%)
Cases unknown as to reaction	4	0	90	16 (17.8%)
Totals	101	27 (16.8%)	3114	462 (14.8%)

†Adjusted to allow for older age distribution and larger proportion of positive blood cultures in cases with history of asthma.

Moreover, the mortality rates from pneumonia among patients with or without a history of asthma were not significantly different whether or not immediate serum reactions occurred.

In view of these findings, and in the absence of contradictory data in the medical literature, it is fair to conclude that a history of asthma due to other than specific sensitivity to the animal from which the serum is derived is not an absolute contraindication to serum therapy.

It is recognized that injection of horse serum may cause sensitization which increases the dangers of its subsequent administration. However, no evidence can be found in the literature that persons with hay fever or asthma are more easily sensitized with horse serum or rabbit serum than normal persons. Since our series does not contain enough patients who had received serum previously, we are unable to settle this point.

Following a severe injury, so-called "primary shock" frequently occurs. This is really a condition of vascular collapse, in which the tone of the peripheral vessels is diminished reflexly, as a result of nervous or psychic stimuli. The vascular bed is dilated to such an extent that the volume of blood becomes insufficient to maintain an adequate venous return to the heart, and thus an adequate output to the periphery. It may be difficult to distinguish this form of collapse from true secondary shock; therefore, all patients admitted with a feeble pulse and lowered blood pressure should be treated immediately for collapse. This treatment involves administering morphine if there is pain, getting the patient warm with blankets and sometimes hot fluids (tea, of course, in England), and putting the patient in shock position with the feet elevated, because gravity plays such an important part in the pooling of blood. If the patient does not quickly improve under these conditions, true secondary shock is probably present.

Most workers agree that in secondary shock there is an insufficient volume of blood to maintain an adequate peripheral circulation, not because of vasodilation (vasoconstriction is usually present), but because of loss of blood or one of its components. This deprivation may come about in a number of ways. In extreme dehydration as in diabetic acidosis or severe diarrhea, it is caused by a loss of water and electrolytes. On the other hand, in hemorrhage it results from a loss of blood, and in burns or severe trauma it results from the oozing of plasma into the injured area. The immediate effects are concentration of those elements of the blood that are not lost, vasoconstriction, manifested by a cold and clammy skin and a thready pulse, and the subjective symptoms of sweating, thirst, anxiety and nausea. If the state of shock continues long enough, general capillary damage may occur, with leakage of plasma throughout the body, thus further exaggerating the symptoms.

In burns and crushing injuries with marked concentration of the red cells, the treatment of choice is the restoration of the lost plasma. Saline infusions are at best of temporary benefit, since the fluid is rapidly lost from the circulation, thus aggravating the condition by sweeping out the proteins of the blood, which are so necessary for the maintenance of its osmotic pressure.<sup>3</sup> On the other hand, in hemorrhage, the ideal therapy is the replacement of whole blood, since both red cells and plasma have been lost. In normal persons, there is a considerable margin of safety in

circulating hemoglobin, and the patient with an acute hemorrhage develops symptoms from diminished blood volume far sooner than from loss of hemoglobin. Hence, any form of therapy that restores the volume of blood and enables the remaining hemoglobin to circulate adequately is sufficient. After a hemorrhage, the concentration of hemoglobin is little altered at first, but gradually falls as the blood volume is brought back to normal by the production of plasma from the patient's own reserves.<sup>4</sup> However, when the hemoglobin falls below a certain level, this process of hemodilution proceeds only to a certain point.<sup>5</sup> Therefore, when a relatively low hemoglobin value is found to begin with, it seems unwise to administer plasma alone. British experience has borne this out. Whereas plasma is extremely effective in the treatment of most air-raid casualties, its use in the treatment of a small series of patients with bleeding ulcers whose hemoglobins were 50 per cent or less before treatment was frequently accompanied by reactions and a fall in blood pressure.<sup>6</sup>

In addition to the use of various types of parenteral fluid, as discussed above, the treatment of shock involves the administration of oxygen whenever possible,<sup>7, 8</sup> since anoxia is an important cause of capillary damage. Warmth, the Trendelenburg position and morphine are also valuable adjuncts to therapy.

There are a number of ways in which whole blood can be made available in emergencies. In the German army, men are assigned to detachments according to their blood groups, so that if any person in a particular unit needs a transfusion he may receive one from another member of the group. This is scarcely applicable to civilian populations. A second method is the listing of all universal donors,\* who comprise some 45 per cent of the population. These people can then serve as donors in emergencies. If care is taken to eliminate those universal donors who have high titers of isoagglutinins, this is a feasible step, since it is usually those with high titers who cause the trouble that inevitably occurs when universal donors are used indiscriminately.

Witebsky et al<sup>9</sup> have recently shown that it is possible to obtain in pure form the A and B factors that are responsible for the specificity of the red cells of Groups A and B. These are mixed in the proper proportion in sterile ampoules, and the contents of an ampoule, when added to 500 cc. of Group O blood, instantly combine with and neutralize the agglutinins. This blood can then be used indiscriminately without previous cross-

\*Group O by the international nomenclature, Group IV by Most, or Group I by Jansky.

matching Witebsky emphasizes the fact that the blood must be taken from a true universal donor, and suggests that such donors be grouped not only by testing their cells against known serums, but also by testing their serums against known cells. These group factors are nonantigenic, and the subjects do not develop an increased titer of isoagglutinins as a result of the injection of blood neutralized with this material. Witebsky reports quite a large series of successful transfusions of this type. Further experience will be necessary before this type of transfusion can be recommended for any but emergency use. Wiener and his co-workers<sup>10</sup> report a reaction from a second transfusion of Group O blood in a patient of another group. The recipient developed anti O agglutinins as a result of the first transfusion, which reacted with the donor's cells on the second transfusion. Thus, the repeated use of neutralized Group O blood might be dangerous.

It is probable that fresh blood will not be used so much for emergencies as stored blood, since the latter can be kept on hand in adequate amounts and is ready for use at any time. There has been an enormous amount of work on stored blood since the institution of blood banks in many hospitals in this country. The use of cadaver blood has been recommended by certain Russian investigators.<sup>11</sup> It does not require the addition of an anticoagulant, and large amounts of it may be obtained from a single donor. However, when very large amounts of blood are necessary, the difficulties of such collection are too great and its advantages too slight to make it practicable. Placental blood has likewise been used<sup>12, 13</sup> and should provide a valuable supply of blood for the preparation of plasma in general hospitals. It has a low isoagglutinin titer and a low lipid content, giving a very clear plasma.<sup>14</sup> Ham<sup>15</sup> has recently discussed the relative advantages of fresh and stored blood. For the treatment of shock and hemorrhage, stored blood is as effective as fresh blood, and sufficient case reports are now available to show that the incidence of reactions is no greater.<sup>16, 17</sup>

The changes that take place in stored blood have been the subject of exhaustive study by a number of investigators<sup>18-25</sup> whose results are in general agreement. Certain components of the blood deteriorate very rapidly. These are the leukocytes, particularly the granulocytes, which disintegrate within the first two or three days, and the platelets, which likewise disappear very rapidly. The prothrombin and complement titers fall off some-

what more slowly, whereas the red blood cells do not diminish appreciably in number for a much longer period. Since it is the plasma and red blood cells that are important in the treatment of shock, a great deal of attention has been paid to methods of preservation that will prevent the hemolysis of red blood cells. With the ordinary citrate anticoagulant in use in most hospitals, stored blood should not be used after more than ten days, because at the end of this time an appreciable proportion of the red cells have begun to hemolyze. Certain measures are effective in the prevention of hemolysis. The exclusion of air by filling the bottle as full as possible is helpful, particularly when blood is to be transported, since there is less agitation of the red cells under these circumstances. Dilution is also an effective means of diminishing hemolysis, but the addition of glucose is most important. This discovery is not new, but goes back to the work of Rous and Turner<sup>26</sup> in 1916. DeGowin and his co-workers<sup>27</sup> have given a great deal of attention to these problems and use a modification of the Rous-Turner anticoagulant mixture routinely. Five hundred cubic centimeters of blood is drawn into a bottle containing a mixture of 650 cc of 5.4 per cent anhydrous dextrose and 100 cc of 3.2 per cent dihydric sodium citrate in water chilled to  $-5^{\circ}\text{C}$ . The blood is drawn into a bottle of such capacity that, when mixed with the anticoagulant, the container is almost completely filled. Blood taken in this way can be used up to thirty days after bleeding without any increase in the incidence of reactions. DeGowin and Hardin<sup>28</sup> have shipped blood by truck and by plane for many miles in iced containers and have used it after transportation in an attempt to show that this is a practicable procedure for military use. Furthermore, DeGowin and his associates<sup>29</sup> have shown that the incidence of reactions is not increased by administering blood as soon as it is removed from the refrigerator or iced container. DeGowin's recommendations deserve serious consideration, and, where hospital blood banks are in operation, the use of this particular anticoagulant mixture is to be commended, since it will at least double the useful life of stored blood. The drawback is that the blood is diluted, and therefore a larger volume has to be administered with each transfusion, which is a disadvantage when congestive failure or hypertension is present. Also, the increased bulk uses up valuable space in transportation.

Various modifications have been proposed to reduce the dilution factor. Denstedt and his co-workers<sup>30</sup> recommend the following: blood 5 parts, 3.2 per cent sodium citrate 1 part and 5.4 per cent dextrose 1.5 parts. Lewisburg<sup>31</sup> used 300 cc. blood and 150 cc. of an anticoagulant mixture containing 1.05 per cent sodium citrate and 3 per cent dextrose in 0.85 per cent saline solution. Barton<sup>32</sup> takes blood into 2.5 per cent sodium citrate solution and adds 50 cc. of 25 per cent aqueous dextrose solution for every 500 cc. of blood after the blood is drawn.

<sup>11</sup>Witebsky<sup>11</sup> summarizes the published literature on the incidence of Grade III reactions (frank chills) as follows: fresh blood (100 transfusions) 6.0 per cent; stored blood (1973 transfusions) 4.7 per cent.

Considerable attention has been directed to the rise in potassium content of the plasma during the storing of blood.<sup>32-34</sup> This is not the result of hemolysis, since the potassium level rises to a peak of between 60 and 100 mg. per 100 cc. in the first five days of storage, and does not increase so fast thereafter. It probably diffuses from the red cells in addition to being liberated by the disintegrated white cells. Blood with this potassium content has been shown to be innocuous by DeGowin et al.,<sup>35</sup> although some workers have suggested that certain unexplained reactions have arisen from its use. The sodium content of the red cells becomes about four times normal during storage, and this produces an increase in the sodium content of the red blood cells of the recipient after transfusion. However, within twenty-four hours, the sodium content of the recipient's red blood cells returns to normal, indicating the restoration of cell electrolyte balance, once these abnormal cells are put into circulation.<sup>36</sup>

Several groups of workers<sup>36-38</sup> have studied the fate of the red cells of stored blood after transfusion. This is done by various modifications of the technic devised by Ashby. Such studies indicate that the cells of stored blood survive nearly as well as the cells of fresh blood, provided the cells do not show an increase in fragility or the blood an appreciable amount of hemolysis before it is used. Certain cells of stored blood become more fragile on storage, and, once transfused, these cells are hemolyzed in the body of the recipient. Thus with ordinary citrated blood kept longer than seven days,—in which tests show that an increased in vitro fragility is present,—bilirubinemia and jaundice may develop in the recipient during the first twenty-four hours.<sup>37-39</sup> Even under these circumstances, it is pointed out that an appreciable number of the red cells survive and that iron from the hemolyzed cells may be utilized to produce new hemoglobin. Wiener and Schaefer<sup>39</sup> have shown that every day of storage in citrate diminishes by about six days the life of a red cell after transfusion, and that it is therefore bad practice to use blood kept more than ten days with plain sodium citrate solution, or more than thirty days with dextrose-citrate solution. They also claim that dextrose, when added to the anticoagulant, increases the life of the cell after transfusion as well as before.

A final point of significance in the use of stored blood is the necessity for having a filter of some type in the outflow line. Small clots are prone to form in both citrated plasma and blood on storage in the cold, and it is essential to use some

method of removing such clots if reactions are to be avoided. Various types of filters, of wire or gauze mesh, have been devised and are available in most commercial outfits.

Although blood is ideal for the treatment of hemorrhage as suggested above, plasma may be used to restore the blood volume and maintain an effective circulation. In crushing injuries, burns, peritonitis and pulmonary edema from poison gases, shock occurs mainly from the loss of plasma, and plasma is not only satisfactory but far better than blood as a therapeutic agent. Since plasma can be kept much longer than blood and, when pooled, can be used without previous cross-matching, it has come into wide use in emergency therapy. Many papers<sup>40-45</sup> in the literature stress the value of plasma in the treatment of secondary shock, both experimental and clinical. It has been used on a wide scale in England in the treatment of shock and acute hemorrhage, where it has become customary to give 500 to 1000 cc. to a shocked patient, and if further therapy is necessary 500 cc. of blood before administering more plasma.<sup>46\*</sup> The studies of a number of workers, particularly Scudder and his associates,<sup>43</sup> have emphasized the benefit of simple observations such as the hematocrit, hemoglobin and plasma specific gravity values in following shock patients, because they give valuable information *before changes in blood pressure occur*. In air-raid casualty stations, little more is possible than an estimation of the hemoglobin content of the blood and a close watch of the patient's blood pressure. All the English workers have pointed out that blood pressure is a far more reliable guide than pulse rate, and that the effect of the administration of plasma on the hemoglobin content of the blood is a very good index of whether blood as well as plasma is necessary.<sup>40†</sup> If the hemoglobin is lowered well below normal by the administration of a liter of plasma, the patient should receive some whole blood. As pointed out above, when the hemoglobin is already quite low as a result of spontaneous hemodilution, prolonged oozing of blood or previous anemia, the administration of plasma may be harmful.

Pooled plasma can be used in extremely large

\*Some idea of the volumes of blood and blood substitutes necessary for the treatment of severely shocked patients may be obtained from a report of the treatment of an injured flyer of the Royal Air Force, who received 2160 cc. of pooled plasma and 2700 cc. of Group O blood in sixteen hours, with eventual recovery.<sup>47</sup>

†Bushby, Kekwick and Whitby<sup>40</sup> point out that the blood volume, and hence the approximate amount of blood lost (by subtracting the blood volume from the normal estimate of 40 cc. per pound), can be calculated after plasma transfusion by the following formula:

$$\frac{\text{Blood volume (cc.) before plasma}}{\text{Hematocrit or hemoglobin per cent after plasma}} = \frac{\text{Blood volume (cc.) + plasma (cc.) given}}{\text{Hematocrit or hemoglobin per cent before plasma}}$$

doses without cross-matching. Levinson and Cronheim<sup>50</sup> have shown that the isoagglutinins in a particular sample of serum are markedly decreased if it is mixed with several other samples of human serum. These observations have been extended and amplified by British workers,<sup>51</sup> and it is apparent that this suppression of the isoagglutinins results from their neutralization by blood-group substances A and B present in the plasma. The proportion in which plasmas should be pooled depends on their relative agglutinin contents, but a formula that has been used with success in England depends on mixing two parts of Group O plasma with four parts of Group A plasma and one part of Group B plasma. Many workers merely pool eight to ten plasma samples without regard to blood groups.<sup>52</sup> It is possible that a plasma with a very high agglutinin content pooled in this routine fashion might still cause trouble, and if hemolytic reactions occur with pooled plasma, the isoagglutinin content of the pool should be determined.

The use of plasma in the treatment of shock is a vital subject and one in which a great many disputes are going on among workers in the field. The first dispute concerns the method of preservation and preparation of the plasma. If plasma is not separated in the first two days after the blood is drawn, its potassium content will be relatively high. However, there is little evidence that this is particularly harmful. In most blood banks, it is now the custom to separate the plasma after the expiration date of the stored blood, although it doubtless would be ideal to separate the plasma in the first twenty-four hours. A number of methods have been devised for preservation. If plasma is to be preserved in its liquid state, there are two dangers: first, the formation of small clots, which can be taken care of by using a filter in the apparatus for injection, and secondly, bacterial contamination.<sup>53, 54</sup> Experiments by British workers<sup>55</sup> have shown that no antiseptic or bacteriostatic agent is very satisfactory in plasma. Proflavine in a dilution of 1:100,000 is probably the best, but is not effective for more than two or three days. The sulfonamide drugs, although quite effective as bacteriostatic agents in whole blood stored in the cold, are not effective in plasma stored either in the cold or at room temperature. Therefore, very strict asepsis must be maintained in all the processes of collection, pooling and bottling of plasma. If possible, everything should be done with a closed system, and the English have come to the conclusion that if plasma is to be kept in the liquid state for any length of time it must

be passed through a bacteriologic filter to ensure sterility. It is very difficult to filter plasma through a Seitz filter, which is the most convenient type to use, because calcium present in the asbestos filter pads combines with the citrate and clotting occurs. Bushby and his co-workers<sup>56</sup> have devised a method for washing the pad intermittently with a strong citrate solution, so that the plasma may be filtered in reasonable amounts. Thalhimer<sup>57</sup> removes most of the calcium from the pads by soaking them in hydrochloric acid. Another group of workers<sup>54</sup> in England add a solution of calcium chloride to the plasma in a flask containing glass beads. The plasma is then agitated. As clotting occurs, the clot is broken up into small masses by the agitation, and a large yield of serum is obtained. This defibrinated fluid can be filtered readily through a Seitz filter and, although it contains a considerable amount of calcium, has apparently been used without reactions.

Probably the most effective way to preserve plasma is to freeze it.<sup>58</sup> In hospitals, where refrigeration is no problem, this is the ideal method. The plasma may be separated by centrifugation in closed bottles, aspirated aseptically into a pooling bottle, reaspirated into 250-cc. or 500-cc. bottles as pooled plasma, and frozen within a few hours of being drawn. It may be frozen and stored in an ordinary low-temperature mechanical refrigerator used commercially for frosted foods, which maintains a temperature of -10 to -15°C. It can be kept in this manner for very long periods without danger of bacterial contamination, or deterioration of such unstable fractions as prothrombin and complement. When ready for use, it may be rapidly thawed at 37°C. and administered to the patient.

When refrigeration is impossible, dried plasma can be used. Three general methods of drying have been advocated.<sup>59-61</sup> The first, originally designed by Thalhimer<sup>59</sup> for the concentration of convalescent serum, consists in rotating the plasma in cellophane bags in a stream of warm dry air. The water evaporates, until finally the plasma solids are left as a dry powder in the bag. This method, which has been advocated by Hartman<sup>60</sup> and used successfully by him, is valuable because of its cheapness and simplicity. The second method, which makes use of vacuum distillation as the plasma is sprayed into a heated chamber, seems less effective because it requires heating and the transfer of the product from one container to another, with a consequent danger of contamination.<sup>61, 62</sup> The third method of drying de-

depends on evacuation and consequent evaporation of water from the frozen plasma. One process involves the preliminary rapid freezing of the material, which then remains frozen throughout the evacuation process by virtue of the rapid evaporation of water vapor.<sup>63-67</sup> The other type involves freezing as a result of the evaporation itself, which occurs very rapidly as the pressure in the container falls to nearly a complete vacuum.<sup>68-71</sup> There are variations of these methods, involving the type of apparatus used to trap the water coming off the plasma, but the principles involved are much the same. Such plasma desiccated from the frozen state is very little altered, since it is frozen very rapidly and has an extremely low moisture content. In this state, the plasma will keep for years if it is protected from the penetration of water vapor from the atmosphere. To ensure this, the material must be kept in sealed glass ampoules or else in rubber-stoppered bottles inside evacuated or nitrogen-filled containers. It can be reconstituted by the addition of appropriate amounts of sterile distilled water as normal plasma or concentrated plasma of varying strength. Such dried plasma will obviously be extremely useful as a readily available blood substitute for use in out-of-the-way places.

Besides disputes about the method of preparation and preservation of plasma, there is an argument about whether serum or plasma may be used interchangeably, and another about whether concentrated, dilute or isotonic plasma should be used in the treatment of shock. Adequate evidence is not available on either of these points to date. However, incomplete reports indicate that, for some reason as yet not understood, reactions are more frequent with serum than with plasma, whereas reactions are no more frequent with plasma than with blood.<sup>72-74</sup> Those who have had experience with the preparation of serum do not seem to have had many reactions with their own product,<sup>54, 75-78</sup> but serum cannot be recommended for general use until more evidence regarding its innocuousness is at hand. Its main virtue is that it does not clot on passage through a Seitz filter, and hence it is more easily prepared on a large scale.

The dispute concerning the value of concentrated plasma or serum cannot be settled. Hill and his co-workers<sup>79-81</sup> have used four-times concentrated plasma a great deal in the treatment of shock in hospital patients, and their clinical results seem very favorable. In certain English reports, concentrated serum produced reactions, and often thrombosis of the vein, but this product

was concentrated by partial evaporation of the water from the serum, and had not been reconstituted from the dried state. It seems reasonable to expect that concentrated plasma is effective in the treatment of shock when adequate reserves of fluid are present in the tissues. On the other hand, in the presence of dehydration, the administration of a hypertonic solution is obviously contraindicated. More work will need to be done on this phase of the question.

An entirely new approach to therapy with blood plasma has been proposed by Cohn and his associates.<sup>82</sup> Instead of using whole plasma for every condition, he proposes to use fractions of the plasma for specific purposes. In shock, the important point is to restore blood volume. The most useful fraction of blood plasma in maintaining blood volume is albumin, which by virtue of its greater net charge and smaller molecular size, plays a greater role than the globulins in maintaining the normal osmotic relations of the blood and tissue fluids. Serum albumin is not only present in greater amounts than the other serum proteins, but also, because of its physicochemical properties, more stable and more soluble. These properties render it a theoretically ideal substitute for whole plasma in the treatment of shock.

This work has been made possible by the development in Cohn's laboratory of methods of fractionation of the plasma proteins whereby large-scale production is made feasible.<sup>83</sup> This depends on the substitution of alcohol—a cheap, commercial reagent that can be distilled off, condensed and used again—for ammonium sulfate as a precipitant. The precipitation is carried out in cellophane cylinders immersed in mixtures of alcohol and water, in which the concentration, pH and temperature are carefully controlled. The precipitate of albumin obtained can be readily dried, since it carries only a small volume of alcohol and water down with it, both of which are volatile at low pressures. Once dried, the material can be stored without precautions, and can be dissolved in buffered saline to any desired concentration when needed. Twenty-five per cent solutions of human albumin pass readily through a Seitz filter. The ease of sterilization and great solubility of this material make it possible to prepare highly concentrated solutions that take up very little space and are remarkably stable. The compactness and low viscosity of this human albumin preparation make it an exceedingly convenient form of substitute for whole blood, since it does not have to be reconstituted like dried plasma and is considerably less bulky. Clinical trials with

concentrated human albumin are under way, and it may play a very useful role as a therapeutic agent for the treatment of shock in emergencies.

Some of the earliest attempts at blood transfusion were made with heterologous blood, and usually resulted in fatal accidents. However, with the advent of plasma transfusion, interest has been revived in the use of heterologous plasma. Wangensteen and his associates<sup>84</sup> have used bovine plasma as a convenient form of plasma protein for parenteral administration to surgical patients unable to take food by mouth. His experiments have shown that bovine plasma can be administered in large doses to human beings, without fatal reactions. A number of moderate reactions occurred, but he successfully treated one patient in shock from an acute gastrointestinal hemorrhage. In following up Wangensteen's work, bovine plasma has been used as a source of purified albumin.<sup>85</sup> Work with this material is under way at present, but is still in the experimental phase. Immediate reactions are fairly well eliminated by the use of a sufficiently pure bovine albumin instead of whole plasma. The incidence of sensitization to beef products and serum disease with such a highly purified albumin is being carefully investigated.

Keys and his associates<sup>86, 87</sup> have recently noted their interest in this problem. They have separated albumin fractions from the serums of a number of animal species, but apparently have not been able to find any nonantigenic heterologous proteins for use in man.

It is too early to evaluate work of this type, but it represents an important experimental approach to the problem of providing cheap and readily available blood substitutes.

Other solutions have been proposed for the restoration of blood volume. Crystalloid solutions, such as saline, Ringer's solution and glucose, are of course extremely useful adjuncts to therapy, but their effect in shock is transient, because the fluid is not retained in the circulation. A number of workers have explored the possibility of using hemoglobin as a source of protein that would not only act to restore blood volume by virtue of its osmotic pressure, but would also be able to carry oxygen. Amberson<sup>88</sup> has shown that an animal deprived of most of its blood will remain alive for hours if it is infused with a hemoglobin-Ringer's solution. The trouble with hemoglobin as a blood substitute is that, although relatively innocuous, the molecule is treated as a foreign substance and is excreted to a considerable extent through the kidneys, where it may be precipitated as hematin in the tubules when an acid urine

is secreted, with resulting kidney damage. This is thought to be the mechanism of anuria in transfusion reactions.<sup>89-91</sup> A number of workers have recently demonstrated that fairly large amounts of hemoglobin may be given intravenously to human beings without untoward results.<sup>92, 93</sup> If measures to maintain an alkaline urine are adopted, such a hemoglobin-Ringer's solution has interesting possibilities, but it is hard to believe that a substance potentially dangerous in large amounts can replace the other proteins that are retained so much more effectively in the blood stream. Six per cent gum acacia in saline was introduced in World War I as a solution possessing the osmotic and viscous properties of blood.<sup>94</sup> Many of the results in shock were excellent.<sup>95, 96</sup> However, the evidence indicates that the gum is deposited in the liver cells, and the possibility of producing permanent liver damage cannot be dismissed too lightly when it is planned to use very large doses.<sup>88-97</sup> Taylor,<sup>98</sup> in Canada, has devised a solution of fish gelatin or isinglass, which seems to be relatively nonantigenic, and which in acute experiments in dogs was able to restore blood pressure after hemorrhage. Comparative studies<sup>99</sup> of various solutions in the therapy of acute hemorrhage in cats showed that gum acacia, hemoglobin-Ringer's solution, dilute plasma and serum were inferior to isotonic plasma and blood.

Another type of solution that may have properties of considerable value in the postoperative care of wounded patients is casein hydrolysate, which Whipple and his co-workers<sup>100</sup> and others<sup>101, 102</sup> have shown to be an extremely powerful stimulant to plasma-protein production when given intravenously. It should not be employed in the treatment of shock, but may be used in patients unable to take protein food by mouth. It consists of a mixture of amino acids and polypeptides derived from casein by enzymatic digestion.

From the practical standpoint, whole blood is unquestionably the ideal substance for the treatment of acute hemorrhage. Since it is not instantly available for use in the field and cannot be stored without refrigeration, plasma forms a very valuable substitute for immediate therapy, which can later be supplemented by blood transfusion when necessary.\* Human albumin, by virtue of its convenient form, may turn out to play a valuable role in emergency treatment. Plasma and

\*After removal of plasma, the remaining red-cell suspension may be used in the treatment of anemic patients.<sup>103</sup> The amount needed may be calculated from a modification of Marriott and Kelwick's formula<sup>104</sup>:

$$\frac{\text{Per cent rise in hemoglobin desired}}{100} \times \frac{\text{Normal blood volume (cc.)}}{\text{Whole blood (cc.) required}} =$$

albumin are superior to blood in the treatment of burn shock. The use of gum acacia will probably be restricted to nephrotic edema, in which it may be more valuable than any form of plasma protein because it is not excreted in the urine.<sup>105</sup>

## NEW TYPES OF TRAUMATIC INJURIES

### *Blast Injuries*

During World War I, a number of cases were observed in which death occurred without detectable injury. Such deaths from apparent concussion have occurred in the present war among people who were close to the points of explosion of large bombs. A considerable amount of experimental work has been done in England by Zuckerman<sup>106</sup> on the pathogenesis of this type of injury, and it has been found that pulmonary lesions are quite constant. These consist mainly of hemorrhages into the substance of the lung and the alveoli, with some bleb formation under the pleural surfaces, on which scattered petechial hemorrhages may be seen. Blood is usually found in the upper air passages, and x-ray films show various changes, including emphysema, mottled areas and patches of atelectasis. His investigations have shown that these injuries are produced by the pressure wave of the blast and not by the subsequent low pressure, as was first supposed. Covering the animals with a heavy layer of sponge rubber prevented the pulmonary lesions and protected the animals from the effects of the blast.

Two series of human cases have been reported. One group of patients known to be exposed to blasts at close range was studied from eight to ten days after the primary injury, but the findings were somewhat inconclusive.<sup>107</sup> The other group consisted of fatal cases in which post-mortem examination showed changes very similar to those found in the experimental animals.<sup>108</sup> In a few cases, lethal concentrations of carbon monoxide were demonstrated. The significance of this syndrome is that considerable hemorrhage may take place in the lungs without clinical symptoms. Therefore, patients known to have been exposed to blasts at close range should be kept under observation longer than their apparent condition warrants, since the x-ray and pathologic changes are always greatly in excess of the symptoms. The similarity of these cases to what has been referred to as traumatic pneumonia, occasionally observed in civilian practice, is striking. All observers agree that, although the pulmonary lesions may be important, they are not the cause of

death, but merely one manifestation of the injury sustained by the organism.

Another syndrome of great interest, which has been described, so far as I know, for the first time during this war, is uremia complicating crush injuries, particularly of the extremities. A number of cases have been reported in the recent British literature of patients who sustained injuries of moderate or marked severity in which there was crushing of muscle tissue.<sup>109-112</sup> In these patients, after apparent recovery, oliguria developed, then anuria, edema of the crushed limb, azotemia and finally death on the sixth to eighth day after the injury or, in some cases, gradual recovery. The urine in such cases, when any was passed, was positive to benzidine, showed coarse brown granular casts, and was rather dark. Studies of the blood of these patients showed, in addition to a high figure for nonprotein nitrogen and a progressive acidosis, a marked rise in the concentration of serum potassium. The pathogenesis of this type of uremia was not understood at first, but Bywaters and Delory,<sup>113</sup> who described some of the first cases and who have studied the condition intensively, have shown that the pigment excreted in the urine that gives the benzidine reaction is not ordinary hemoglobin, but myohemoglobin. This pigment, of course, is derived from muscle, presumably in the injured area, and the likeliest explanation for the uremia seems to be the precipitation of myohematin in the renal tubules, producing anuria in the same manner as hematin after a hemolytic transfusion reaction. This suggests that the administration of fluids and alkali is advisable as early as possible for patients trapped in such a way that crushing injuries are incurred.

## CONTROL OF AIR-BORNE INFECTIONS

Last year's review<sup>114</sup> mentioned briefly some of the possibilities in the control of air-borne infections, which constitute the most serious menace to health in crowded air-raid shelters. Respiratory diseases are the most difficult of any group of communicable diseases to control, and English and American workers have been studying this problem intensively in the past year. Their findings may prove of great value in the large military camps of the United States.

A recent report by Andrewes<sup>115</sup> summarizes his work and that of his colleagues. It points out that air-borne infection travels in three ways. The first is by coarse droplets, which are projected into the atmosphere by sneezing and coughing and

fall to the floor in a short time because of their size. Control of this form of spread is possible by adequate screening of individual patients and by proper masks, the most effective one that the English have found being made of a sheet of cellophane, which is impermeable to bacteria and viruses. It is worth pointing out that in the Boston Lying-in Hospital a mask consisting of a layer of nonabsorbent cotton folded into a layer of gauze has been used for some time. This utilizes the principle that bacteriologists have used for many years to exclude bacteria of the air from their cultures, and is highly effective. Since such a mask is cheap and can be discarded after use, it should replace the ordinary gauze mask used by most hospitals.

The second form of air-borne infection is by droplet nuclei. These are minute droplets, so small that they remain in suspension in the air for long periods. Each droplet nucleus may contain a few bacteria, and it is in this form that infection is borne about in the air through buildings, as has been demonstrated most clearly by the work of Wells and Wells.<sup>110</sup> Possibly, this type of infection can be controlled by the use of ultraviolet light. The English workers suggest that the air in shelters be drawn through a heavy muslin screen, which will serve as a filter for large droplets, then through a tunnel, in which ultraviolet lights are placed, and then ejected as sterile air into the room again. This is more effective and less expensive than placing ultraviolet lights about a room, as has been done in operating amphitheatres. Another method of combating droplet nuclei is by the use of aerosols. This development is due mainly to the studies of Trillat<sup>117</sup> and Twort et al.<sup>118</sup> Aerosols are antiseptic liquids nebulized in such a way as to form minute droplets much like the droplet nuclei mentioned above. These then remain suspended in the air for long periods as a fine mist, which is unnoticed by anyone present in the room. By such fine dispersion, a small amount of the liquid will fill quite a large room, and yet in each individual droplet the antiseptic solution can be kept at an effective level. Droplet nuclei and bacteria are attracted to the aerosol droplets, and the bacteria are killed by the antiseptics present in them. Hexylresorcinol in propylene glycol is the most effective known aerosol, but sodium hypochlorite can be used in 0.5 per cent solution very effectively without irritation to the mucous membranes. The British are experimenting with the use of these aerosols in the sterilization of shelters immediately before and after their occupation.

The third way in which bacteria are carried in the air is by dust. Droplets fall to the floor, the water evaporates, and the bacteria, particularly hemolytic streptococci and diphtheria and tubercle bacilli, may remain viable for long periods, to be swept up in the air with any disturbance. In this form, the organisms are resistant to ultraviolet light. Likewise, they are present on blankets, and it has been shown that the bacterial count of the air rises following bed-making in a hospital ward. To control this type of infection, the British workers have found the application of oil to be most effective. Mineral oil is rubbed on the floors, and although a certain amount of luster is lost, sweeping of floors so treated will not throw bacteria up in the air. Hospital blankets can be treated in such a way with mineral oil in naphthalene or some similar solvent that the blankets appear perfectly normal. However, they retain about 3 per cent by weight of oil, and this suffices to trap bacteria.

\* \* \*

This brief report on progress in military medicine shows that the necessities of war have served as a stimulus to research that may have a vital bearing on medical practice and the prevention of sickness in peace as well as in war.

We are not told on physical examination whether he did or did not have any tophi. Regardless of this fact, I think the diagnosis of gout is the most likely one. The patient had recurrent attacks in one or another of the big toes, presumably in the metatarsophalangeal joint. It is interesting that, as the swelling of the feet subsided, the gout became more noticeable; this is proof of the well-known fact that an attack of gout can be provoked by induced or spontaneous diuresis. It is extremely unlikely that the joint disturbances could be due to infectious or rheumatoid arthritis, which, over a period of years, would most certainly have resulted in joint disability between attacks. The entire clinical picture during the five months previous to entry is perfectly compatible with gout.

It is interesting that the patient was pale and slightly short of breath, with blood in his nose, and some explanation of that should be made. The urine showed a ++++ test for albumin. The urine concentration test showed a specific gravity of 1.011, and a phenolsulfonephthalein test showed no excretion of the dye in two hours. That is the first definite clue that there was something very wrong with the kidneys. The blood picture showed a moderate normochromic anemia. So far as the diagnosis of gout goes, the uric acid level of 10.3 mg. per 100 cc. is of no help, because it is elevated in every case of renal insufficiency with marked nitrogenous retention. Is the uric acid more elevated in relation to the non-protein nitrogen in the presence of both gout and uremia? I do not know, but I think so. The formol-gel test is positive in most cases of cirrhosis of the liver. I am a little disturbed that the liver function, as measured by dye excretion, was so good, and that the serum van den Bergh was normal. I should expect, in a typical case of portal cirrhosis, a slight degree of dye retention. Nevertheless, that does not mitigate against the diagnosis of portal decompensation. Of course, in any person with cirrhosis of the liver who vomits or passes blood, our first thought concerns varices in the esophagus. On the other hand, the fact that the x-ray film did not show them does not rule them out. We know that in alcoholism there are other causes for vomiting; one that might result in a severe hemorrhage and still not be seen by x-ray is severe gastritis. So far, we have no evidence for or against that diagnosis.

X-ray examination showed a fair degree of narrowing of the joint spaces in the feet, with a certain amount of atrophy. The hands showed little except degenerative changes. In other words,

the x-ray picture was compatible with a diagnosis of gout, that is, it showed very little bone or joint change. On the other hand, even if the findings were more marked than these and even if they simulated rheumatoid arthritis more seriously, they would be compatible with gout, as we have seen in quite a few cases in this hospital.

The electrocardiogram was not significantly abnormal.

According to the record, the cervical spine was involved. That is disturbing, if true, because by and large it is extremely rare for acute gout to involve any part of the cervical, dorsal or lumbar spine. I rather imagine that this probably represents acute tenosynovitis in the ligaments or tendons of the neck.

There was a very marked degree of hypocalcemia, high phosphorus retention due to kidney insufficiency, and marked acidosis, with only 50 per cent of the normal carbon dioxide combining power. One would certainly expect a patient with a calcium of 6.3 mg. per 100 cc. to have a positive Chvostek's sign. I rather imagine that this patient did not have it because of the high degree of acidosis.

The sodium citrate and aluminum hydroxide were given presumably to try to normalize the calcium-phosphorus metabolism; however, eight days later it was about the same. We are not told whether the patient received specific therapy for the gout, such as colchicine.

We are now faced with the terminal event, and we are unable to obtain further information about the fundamental diagnosis. In a person of sixty-two with hypertension and gout, I should say the most likely thing would be a severe degree of nephrosclerosis, a terminal vascular disease in the kidneys. There is nothing in the past history to suggest acute or subacute glomerulonephritis, any infectious type of nephritis, pyelonephritis or any other type of renal disease. I say "with gout" because renal vascular disease is commoner in people with long-standing gout than in other people.

Is this a gouty nephritis? I think it has been decided that we do not know exactly what gouty nephritis is. True, some people at autopsy show high degrees of vascular change and some uric acid crystals in or around the tubules. I should say that if this attack was acute it was not due to a primary type of renal disease.

In the record of the last admission, there is a definite change in electrocardiographic findings from what was previously recorded—a low T<sub>1</sub> five days after acute chest pain. Five days later, T<sub>1</sub> was diphasic. In view of the history, the

electrocardiographic findings, the clinical findings and the acute cardiac decompensation, there can be little doubt that there was coronary occlusion, with an infarct of the anterior type. We are not told very much at the time of the last admission about the amount of fluid in the abdomen or the feel of the liver after paracentesis. There is no question that the terminal event was coronary occlusion and cardiac failure.

He also had blood in the stools as a terminal event. Whether that was bleeding from esophageal varices or gastritis or possibly from the hiatus hernia, which is rather unlikely, or a uremic colitis, it is impossible to say.

I have mentioned most of the differential diagnoses, and I sum up the list of probable diagnoses as follows: gout, portal cirrhosis, arteriosclerosis, hypertension, nephrosclerosis with uremia, coronary occlusion with cardiac failure, and questionable gastritis or esophageal varices as the cause of the bleeding. I should like to add that I am still disturbed by the fact that the liver is reported to have felt smooth and round. I do not recall ever having seen a case of portal cirrhosis in which the liver felt smooth.

DR ALFRED KRANES: Do you not think that, clinically, the liver is always smooth in portal cirrhosis?

DR JACOBSON: I think it is irregular. DR KRANES: Do you think one can always feel the small nodes clinically?

DR JACOBSON: No, I mean after paracentesis, when the abdomen is flat.

DR TRACY B. MALLORY: I should be inclined to agree with Dr. Kranes. I am skeptical if anyone feels irregularities in a cirrhotic liver. At the stage when the liver is big enough to be felt, the granules that are present are particularly small, and it seems to me that it would be impossible to feel them.

#### CLINICAL DIAGNOSES

Gout  
Chronic glomerulonephritis  
Uremia  
Cirrhosis of liver

#### DR JACOBSON'S DIAGNOSES

Portal cirrhosis  
Hypertension  
Generalized arteriosclerosis  
Nephrosclerosis  
Uremia  
Gout  
Coronary occlusion  
Cardiac failure  
Gastritis (?) or esophageal varices (?)

#### ANATOMICAL DIAGNOSES

Gout  
Alcoholic cirrhosis of the liver  
Splenomegaly  
Esophageal varices  
Chronic vascular nephritis  
Uremic colitis  
Hypertrophy of the heart  
Bronchopneumonia

#### PATHOLOGICAL DISCUSSION

DR MALLORY: At the post mortem examination, no tophi were discovered. Many of the joints showed extensive urate deposits. About 5 liters of ascitic fluid was found.

The liver was larger than normal, and possibly a reason for the smoothness was the fact that it was rather markedly frosted with a heavy layer of white fibrous tissue, so that even a 1 cm. nodule certainly could not have been felt. The cut surface of the liver showed a marked increase in fibrous tissue, complete destruction of the architecture and innumerable little granules of encapsulated liver tissue, the largest of them was 3 mm. in diameter, however, and the vast majority were 1 or 2 mm. Microscopically, it was typical of an alcoholic cirrhosis. The spleen was somewhat enlarged, weighing 350 gm., and also showed a frosted capsule. The esophagus showed very evident varices. It is surprising that they were not shown by the x-ray studies, which often show varices that we have difficulty in finding at autopsy. None of them, so far as we could make out, had bled recently. At any rate, there was no ruptured varix at the time of death. There was no marked grade of gastritis, but the colon showed a very severe hemorrhagic colitis and was filled with a bloody mucous fluid. I think the terminal hemorrhage from the bowel almost certainly came from the colon rather than the esophagus. Some of the earlier episodes of hematemesis probably did come from the esophagus. The colitis was not specific in character and corresponded to what we usually call "uremic colitis."

The heart was hypertrophied, but we could find no infarct, and the coronary arteries were very good, not even markedly narrowed, there was no pericarditis. The lungs were normal.

The kidneys were small, the pair weighing 220 gm. The gross appearance was that of nephrosclerosis. Just after the autopsy, some pieces of kidney were examined under the dissecting microscope, and it was thought that some uric acid crystals could be identified at the time. Later, sections of alcohol fixed material stained specifically for uric acid failed to show it, so that I think

so caused the mild but definite polycythemia, more cells being needed to carry the same amount of oxygen from the limited lung surfaces. It is amazing that the tumor grew to this size and failed to cause urinary changes.

#### CLINICAL DIAGNOSIS

Hypernephroma, with widespread metastases.

#### DR. CHAPMAN'S DIAGNOSES

Portal cirrhosis, moderate.

Multiple lipomas.

Hypernephroma, left kidney, with widespread metastases.

Polycythemia, secondary to obliteration of the lung fields.

#### ANATOMICAL DIAGNOSES

Portal cirrhosis of the liver.

Hepatoma, with metastases to lungs, bone and left adrenal gland.

Tumor thrombi of hepatic vein and inferior vena cava.

Splenomegaly, secondary to portal obstruction.

? Polycythemia vera.

#### PATHOLOGICAL DISCUSSION

DR. TRACY B. MALLORY: This was obviously a very puzzling case from the diagnostic point of view. There were many leads, but each of them seemed to be contradicted by some other finding, or to be absolutely without confirmatory support. It is extraordinary, for example, to find a man dying of metastatic malignant disease with a polycythemia instead of an anemia. The Pancoast syndrome suggested a primary bronchiogenic carcinoma, but the x-ray examination showed clearly that the tumor was outside the lungs. The pyelogram suggested hypernephroma, but the urine was normal and the history of alcoholism and the suspicious evidences of cirrhosis seemed simply a complicating factor. The clinicians on the wards reasoned essentially as Dr. Chapman did, and likewise came to the conclusion that hypernephroma was the best bet. As a matter of fact, the most important lead in the record was the history of chronic alcoholism, for the patient had a cirrhosis and he had that by no means uncommon complication of cirrhosis, a primary liver-cell carcinoma or hepatoma. The roentgenologist was correct in his opinion that the right lobe of the liver was smaller than normal, but the left lobe was more

than correspondingly enlarged and almost completely replaced with tumor. As these hepatomas characteristically do, the tumor had invaded and grown along the hepatic vein up to the vena cava, into which a nubbin of tumor thrombus that narrowed it by a quarter of its cross-sectional area had projected.

It had metastasized extensively, and there were numerous small tumor nodules in the lungs. The tumor responsible for the Horner's syndrome was metastasis to the seventh cervical vertebra, which had grown forward and downward to displace the apex of the lung. It did not invade the brachial plexus and must have produced its effect by pressure only. Another large metastasis had completely replaced the left adrenal gland, and it must have been adhesions from this tumor mass that were responsible for the deformity of the left renal pelvis. The epigastric mass was, I imagine, mostly the left lobe of the liver, although it is possible that the adrenal tumor may also have been felt. The spleen was greatly enlarged, weighing 800 gm., but they apparently were able to dissociate this from the epigastric mass.

I am entirely at a loss to explain the polycythemia. It was certainly greater than could be explained merely by dehydration. The bone marrow showed, besides the major metastatic lesions, recognized by the roentgenologist, multiple milium metastases, and therefore one would have expected an anemia. The portion not involved by tumor showed an extreme grade of erythrocytic hyperplasia, and was consistent with but hardly diagnostic of a polycythemia vera. I had hoped that the spleen might help us make such a diagnosis, but it showed only the marked sinusoidal engorgement and the fibrosis of the pulp characteristic of long-standing portal congestion, such as is seen with cirrhosis of the liver and in the so-called "Banti's syndrome." Dr. Chapman's suggestion of a secondary polycythemia based on pulmonary insufficiency is interesting, but I am unable to agree with him. The extent of metastatic involvement of the lungs was not nearly so great as we frequently see, and I cannot remember ever to have seen a secondary functional polycythemia based on neoplastic replacement of pulmonary tissue.

## POSTGRADUATE MEDICAL EDUCATION

THE 1940 report of the Commission on Graduate Medical Education\* devoted more of its space to the discussion of internships, residencies and specialties than it did to the needs of the practicing physician. The commission is aware of the serious problems involved in this wider field, however, for it acknowledged the need of postgraduate education for family doctors from many points of view. The report stated, "The time is now ripe for the development of broad standards of educational content of postgraduate work, standards that will emphasize objectives and stimulate higher achievement without inhibiting widespread

experimentation with means and methods." Particular attention should therefore be paid to an article appearing in this issue of the *Journal*. If the time is ripe, it appears that the program of Tufts College Medical School for postgraduate medical education offers some of the "means and methods."

Three years of experimentation in this field are worth recording. How much of the present program will be continued and how much will need to be readapted, it is impossible to say. The program as a whole has behind it a broad conception of the problem. It visualizes a medical service that is not rendered by the physician alone, but by a group of people and facilities under the direction of the physician. If the physician wants an electrocardiogram, he must have the facilities for obtaining it, and if he cannot fully understand its implications, he must have help in its interpretation. If he is taught what the clinical laboratory can do for him today, a laboratory and a technician must be made available. If he understands and appreciates the possibilities of modern x-ray technic, proper apparatus must be provided. Much of the discouragement of the alert practicing physician comes from his inability to make his own diagnostic knowledge effective through lack of personnel or material, or both. An initial attempt to supply these deficiencies by paralleling postgraduate education with an affiliated system of regional and community hospitals, including all the usual ancillary activities and services, has been made, apparently with a considerable measure of success. The Bingham Associates Fund appears to have made an auspicious entrance into the field of medical education at Tufts.

## THE TREATMENT OF TRAUMATIC SHOCK

ALTHOUGH the problem of shock has continued to challenge investigators since World War I, the present war has given a great impetus to research in this field. Since shock is a state that is difficult to define, and can come about in a number of ways, it is small wonder that the prob-

TABOR—EDWARD O. TABOR, M.D., of Lowell, died August 25. He was in his sixty-sixth year.

Born in Hanover, New Hampshire, Dr. Tabor received his degree from Dartmouth Medical School in 1901. He was a fellow of the Massachusetts Medical Society and the American Medical Association.

His widow and a son survive him.

## CORRESPONDENCE

### "ACCOUCHEMENTS FOR AMERICA"

To the Editor: Probably doctors know more about economics, politics and other nonmedical subjects than any other group of people, but I humbly beg to differ with the opinion of Dr. Francis H. Higgins on "bargains in babies," which appeared in the August 14 issue of the *Journal*. Our crackpot friends, Herr Hitler and Il Duce, have had similar ideas, but it is emphatically not what we need in this country.

Here is how the scheme would work out: the many intelligent, hard-working and patriotic young couples of the lower middle class would still have only one or two children; they would not feel that they could afford to take advantage of the bargain rates, because they do not have large enough incomes to provide for clothing, food and education for more children. But the people who do not know enough or care enough to limit the number of their children would be encouraged to have even more, if possible, because of the 25 per cent reduction for each succeeding baby. The final result would be an increase in the population, but with an increase in the proportion of those who are relatively unproductive and a corresponding decrease of able professional and technical people. Such a public would eventually welcome a totalitarian government, which would involve, among less important things, regimentation of the medical profession.

Why not put the medical economists to work figuring out some sort of subsidy or bargain rate for the many couples who would like to have more children and who would have more if they felt that they could provide decent living conditions for them? That would be a definitely patriotic step.

## BOOK REVIEWS

*A Surgeon's Life: The autobiography of J. M. T. Finney.* 8°, cloth, 396 pp. New York: G. P. Putnam's Sons, 1940. \$3.50.

Finney, in his autobiography, covers an interesting period in the development of medicine in America. Trained in the best traditions of his time, at the Harvard Medical School and the Massachusetts General Hospital, he went to the Johns Hopkins Hospital when Welch, Osler, Halsted and Kelly were at their height. The seeds sown by these great pioneers had grown to fruit, and Finney, with his colleagues of the eighteen nineties, reaped a rich harvest. Little was added by the second generation, for it was a time of putting into practice the stimulation received from others, not for the development of new ideas. Many of Finney's contemporaries became good surgeons and fine physicians, but none, save Harvey Cushing, were of the genius type of their predecessors. This, in no way, detracts from the excellent work of Finney and his associates, for they did the best surgery in America of their day, and practiced the best medicine. Finney gives an intimate picture of life at Hopkins, but much of the pic-

ture lacks color and shading. The outlines are discernible, but no clear memory remains after reading chapters, for the whole book lacks body and depth. A few stories help to enliven the drab narrative, and Finney's humor and infectious laughter are felt throughout. He always added a story to any group, and was often called on to relieve tense situations in hospital and overseas during World War I. He was the embodiment of sound common sense, the conciliator and the man of sound judgment. One would choose him, however, rather as a surgeon than as an author, and that is a choice, no doubt, that Finney would agree was the most fitting.

*Diseases of the Digestive System.* Edited by Sidney Portis, B.S., M.D. 8°, cloth, 952 pp., with 176 illustrations and 37 tables. Philadelphia: Lea and Febiger, 1940. \$10.00.

This volume should prove to be an extremely useful text and reference book, for it has been carefully compiled by leading authorities. It presents a comprehensive up-to-date study of gastroenterology. The material is arranged in five parts, as follows: "Introduction," with chapters on history, anatomy, physiology and the interpretation of pain in the gastrointestinal tract; "Etiologic Factors," including parasites, neurogenic factors, gastrointestinal manifestations of other diseases, anemias of gastrointestinal origin, tuberculosis, allergy and the relation of the teeth and diet to gastrointestinal diseases; "Diseases of the Esophagus, Stomach and Duodenum," with chapters on the esophagus, gastritis, peptic ulcer, achylia, cancer, benign tumors, syphilis, linitis plastica, duodenal ileus; "Other Diseases of the Digestive System," including affections of the liver, gall bladder, pancreas and small intestine, and regional ileitis and appendicitis; and "Diseases of the Large Bowel and Rectum," including chapters on functional disturbances, protozoal infections, bacillary dysentery, ulcerative colitis, mucous colitis, cancer, diverticulitis, melanosis, hemorrhoids and lymphatic venereal disease.

The reviewer finds little to criticize. Modern methods of study, including gastroscopy and liver-function tests, receive a fair share of attention. Treatment is well considered in each chapter. Numerous references are given. Illustrations, tables and diagrams are very satisfactory. This book is highly recommended.

## NOTICES

### SEVENTH POSTGRADUATE SEMINAR IN NEUROPSYCHIATRY

The Metropolitan State Hospital, Waltham, recently announced the opening of the Seventh Postgraduate Seminar in Neuropsychiatry.

The course consists of three units: military neuropsychiatry, October 3 to 31; general psychiatry, November 3 to December 12; and general neurology, January 3 to April 10. It is open to a limited number of graduate physicians. The teaching staff comprises a number of recognized specialists in this field throughout the state and is under the direction of Dr. Roy D. Halloran, superintendent, Metropolitan State Hospital, and Dr. Paul Yakovlev, clinical director, Walter E. Fernald State School.

### FORUM ON ALLERGY

The fourth annual Forum on Allergy will be held in Detroit, Michigan, on January 10 and 11, 1942.

## THE MOSAIC OF ANDROGYN\*<sup>†</sup>

Maleness Within the Female and Femaleness Within the Male

GEORGE DRAPER, M.D.<sup>†</sup>

NEW YORK CITY

LIKE other bisexual forms, the human species is divided into males and females according to the presence of testes or ovaries, with their accompanying external genitalia. Reproduction is the primary purpose of these opposed organ assemblages. But, in addition to the specific function of race perpetuation, each man and woman must likewise serve the law of self-preservation. This vital individual task, among primitive peoples at least, calls for different kinds of qualities that are adapted to the special relation maintained by each sex toward environment.

So far as one knows, the actual phenomenon of reproduction is achieved through the genital organs alone. A person's other task of survival depends on adequate adjustment with a complex environment, which includes human relations. The impulse to survive is expressed extragenitally by the man in manly fashion, and by the woman in womanly ways. The opposite and special endowments for these purposes are in general well known, and are displayed by differences between man and woman in morphology, physiology, immunity and psychology—or as somatic cellular sex in the total organism. This composite structure of masculine and feminine characters has been called "the mosaic of androgyny" ( $\alpha\mu\beta\iota\sigma$  = male;  $\gamma\omega\gamma$  = female). The term is used because the nongenital qualities appropriate to each sex are never complete in a given man or woman to the exclusion of some evidence of the counterpart. Thus, traits that are ordinarily judged to be the man's may appear in the woman to form kaleidoscopic patterns with her own; the reverse is like-

wise true. The contrasting qualities have to do not only with outward design, structure and function, but even more significantly with the extragenital dynamics of the whole person. So far as the relation of human constitution to disease is concerned, the androgynous phase of sex seems to be of greater significance than the genital. And it is for this reason that the terms "andric" and "gynic" (adjectives formed from the joint word's component parts) have been chosen to designate the divergent organismal aspects of man and woman.

Within certain limits, the expressions of cellular sex in adults are modifiable by castration or its milder physiologic analogue,—the climacteric,—or by tumors of various endocrine glands. A good example of this is the greatly increased emphasis on andric characters in patients with adrenal tumors, as described by Gallais.<sup>1</sup> But even in his Case 3, the late effects of the tumor could not have been related to the existing broad shoulders and narrow hips. These andric characters must have been laid down in the genetic plan, or effected at an early embryonal stage by some intrauterine accident. It goes without saying that sex hormones exert a powerful influence on the entire organism. But the effects of castration, for example, are more extensive in the male. Furthermore, the castrated male tends to take on characters that in many respects are similar to the female. This "toward-female" capacity, however, is more marked in some castrates than in others. Among insects it is known that the various somatic insignia of maleness or femaleness may have no relation to the nature of the gonad. From all these observations it seems that sex is something more than the mere presence of a gonad. As Lillie<sup>2</sup> believes, sex is not "an irreversible predestination, but a quantitative over-
